

# Package ‘seqHMM’

September 25, 2025

**Title** Mixture Hidden Markov Models for Social Sequence Data and Other Multivariate, Multichannel Categorical Time Series

**Version** 2.1.0

**Description** Designed for estimating variants of hidden (latent) Markov models (HMMs), mixture HMMs, and non-homogeneous HMMs (NHMMs) for social sequence data and other categorical time series. Special cases include feedback-augmented NHMMs, Markov models without latent layer, mixture Markov models, and latent class models. The package supports models for one or multiple subjects with one or multiple parallel sequences (channels). External covariates can be added to explain cluster membership in mixture models as well as initial, transition and emission probabilities in NHMMs. The package provides functions for evaluating and comparing models, as well as functions for visualizing of multichannel sequence data and HMMs. For NHMMs, methods for computing average causal effects and marginal state and emission probabilities are available. Models are estimated using maximum likelihood via the EM algorithm or direct numerical maximization with analytical gradients. Documentation is available via several vignettes, and Helske and Helske (2019, <[doi:10.18637/jss.v088.i03](https://doi.org/10.18637/jss.v088.i03)>). For methodology behind the NHMMs, see Helske (2025, <[doi:10.48550/arXiv.2503.16014](https://doi.org/10.48550/arXiv.2503.16014)>).

**LazyData** true

seqHMM-package

*The seqHMM package***Description**

The seqHMM package is designed for fitting hidden (or latent) Markov models (HMMs) and mixture hidden Markov models (MHMMs) for social sequence data and other categorical time series. The package supports models for one or multiple subjects with one or multiple interdependent sequences (channels). External covariates can be added to explain cluster membership in mixture models. The package provides functions for evaluating and comparing models, as well as functions

for easy plotting of multichannel sequences and hidden Markov models. Common restricted versions of (M)HMMs are also supported, namely Markov models, mixture Markov models, and latent class models.

## Details

Maximum likelihood estimation via the EM algorithm and direct numerical maximization with analytical gradients is supported. All main algorithms are written in C++. Parallel computation is implemented via OpenMP for pre-2.0.0 functions, while estimation of non-homogenous models support parallelization via future package by parallelization of multistart optimizations and bootstrap sampling.

---

biofam3c

*Three-channel biofam data*

---

## Description

Biofam data from the TraMineR package converted into three channels.

## Format

A list including three sequence data sets for 2000 individuals with 16 state variables, and a separate data frame with 1 id variable, 8 covariates, and 2 weight variables.

## Details

This data is constructed from the `TraMineR::biofam()` data in the TraMineR package. Here the original state sequences are converted into three separate data sets: children, married, and left. These include the corresponding life states from age 15 to 30: childless or (having) children; single, married, or divorced; and (living) with parents or left home.

Note that the divorced state does not give information on parenthood or residence, so a guess is made based on preceding states.

The fourth data frame covariates is a collection of additional variables from the original data:

idhous	id
sex	sex
birthyr	birth year
nat_1_02	first nationality
plingu02	language of questionnaire
p02r01	religion
p02r04	religious participation
cspfaj	father's social status
cspmoj	mother's social status
wp00tbgp	weights inflating to the Swiss population
wp00tbgs	weights respecting sample size

The data is loaded by calling `data(biofam3c)`. It was built using following code:

```
data("biofam" , package = "TraMineR")
biofam3c <- with(biofam, {

## Building one channel per type of event left, children or married
bf <- as.matrix(biofam[, 10:25])
children <- bf == 4 | bf == 5 | bf == 6
married <- bf == 2 | bf == 3 | bf == 6
left <- bf == 1 | bf == 3 | bf == 5 | bf == 6 | bf == 7

children[children == TRUE] <- "children"
children[children == FALSE] <- "childless"
# Divorced parents
div <- bf[(rowSums(bf == 7) > 0 & rowSums(bf == 5) > 0) |
          (rowSums(bf == 7) > 0 & rowSums(bf == 6) > 0),]
children[rownames(bf) %in% rownames(div) & bf == 7] <- "children"

married[married == TRUE] <- "married"
married[married == FALSE] <- "single"
married[bf == 7] <- "divorced"

left[left == TRUE] <- "left home"
left[left == FALSE] <- "with parents"
# Divorced living with parents (before divorce)
wp <- bf[(rowSums(bf == 7) > 0 & rowSums(bf == 2) > 0 &
```

```

      rowSums(bf == 3) == 0 & rowSums(bf == 5) == 0 &
      rowSums(bf == 6) == 0) |
    (rowSums(bf == 7) > 0 & rowSums(bf == 4) > 0 &
      rowSums(bf == 3) == 0 & rowSums(bf == 5) == 0 &
      rowSums(bf == 6) == 0), ]
left[rownames(bf) %in% rownames(wp) & bf == 7] <- "with parents"

list("children" = children, "married" = married, "left" = left,
     "covariates" = biofam[, c(1:9, 26:27)])
})

```

---

bootstrap\_coefs

*Bootstrap Sampling of NHMM Coefficients*

---

### Description

The model estimation for each bootstrap sample uses the same method and tolerances as the original fit. If you want to change these, you can modify the elements of the input model such as `model$estimation_results$method` and `model$controls` before passing it to `bootstrap_coefs()`.

### Usage

```

bootstrap_coefs(model, ...)

## S3 method for class 'nhmm'
bootstrap_coefs(
  model,
  nsim,
  type = c("nonparametric", "parametric"),
  append = FALSE,
  ...
)

## S3 method for class 'mnhmm'
bootstrap_coefs(
  model,

```

```

    nsim,
    type = c("nonparametric", "parametric"),
    append = FALSE,
    ...
  )

```

### Arguments

model	An nhmm or mnhmm object.
...	Ignored.
nsim	number of bootstrap samples.
type	Either "nonparametric" (default) or "parametric", to define whether non-parametric or parametric bootstrap should be used. The former samples sequences with replacement, whereas the latter simulates new datasets based on the model.
append	If TRUE, in case the model already contains bootstrap samples, new samples are appended to model\$boot. If FALSE (default), old samples are discarded.

### Details

It is possible to parallelize the bootstrap runs using the future package, e.g., by calling `future::plan(multisession, workers = 2)` before `bootstrap_coefs()`. See [future::plan\(\)](#) for details.

`bootstrap_coefs()` is compatible with progressr package, so you can use `progressr::with_progress(bootstrap_coefs)` to track the progress of bootstrapping.

### Value

The original model with additional element `model$boot`.

---

build\_hmm

*Build a Hidden Markov Model*

---

### Description

Function `build_hmm` constructs a hidden Markov model object of class `hmm`.

### Usage

```

build_hmm(
  observations,
  n_states,
  transition_probs,
  emission_probs,
  initial_probs,
  state_names = NULL,
  channel_names = NULL,
  ...
)

```

**Arguments**

observations	An stslst object (see <code>TraMineR::seqdef()</code> ) containing the sequences, or a list of such objects (one for each channel).
n_states	A scalar giving the number of hidden states. Not used if starting values for model parameters are given with <code>initial_probs</code> , <code>transition_probs</code> , or <code>emission_probs</code> .
transition_probs	A matrix of transition probabilities.
emission_probs	A matrix of emission probabilities or a list of such objects (one for each channel). Emission probabilities should follow the ordering of the alphabet of observations ( <code>alphabet(observations)</code> ), returned as <code>symbol_names</code> .
initial_probs	A vector of initial state probabilities.
state_names	A list of optional labels for the hidden states. If NULL, the state names are taken from the row names of the transition matrix. If this is also NULL, numbered states are used.
channel_names	A vector of optional names for the channels.
...	Additional arguments to <code>simulate_transition_probs()</code> .

**Details**

The returned model contains some attributes such as `nobs` and `df`, which define the number of observations in the model and the number of estimable model parameters, used in computing BIC. When computing `nobs` for a multichannel model with  $C$  channels, each observed value in a single channel amounts to  $1/C$  observation, i.e. a fully observed time point for a single sequence amounts to one observation. For the degrees of freedom `df`, zero probabilities of the initial model are defined as structural zeroes.

**Value**

Object of class `hmm` with the following elements:

- `observations`  
State sequence object or a list of such objects containing the data.
- `transition_probs`  
A matrix of transition probabilities.
- `emission_probs`  
A matrix or a list of matrices of emission probabilities.
- `initial_probs`  
A vector of initial probabilities.
- `state_names`  
Names for hidden states.
- `symbol_names`  
Names for observed states.
- `channel_names`  
Names for channels of sequence data.

- `length_of_sequences`  
(Maximum) length of sequences.
- `sequence_lengths`  
A vector of sequence lengths.
- `n_sequences`  
Number of sequences.
- `n_symbols`  
Number of observed states (in each channel).
- `n_states`  
Number of hidden states.
- `n_channels`  
Number of channels.

)

```

**Description**

Function `build_lcm` is a shortcut for constructing a latent class model as a restricted case of an `mhmm` object.

**Usage**

```
build_lcm(
  observations,
  n_clusters,
  emission_probs,
  formula = NULL,
  data = NULL,
  coefficients = NULL,
  cluster_names = NULL,
  channel_names = NULL
)
```

**Arguments**

<code>observations</code>	An <code>stslst</code> object (see <code>TraMineR::seqdef()</code> ) containing the sequences, or a list of such objects (one for each channel).
<code>n_clusters</code>	A scalar giving the number of clusters/submodels (not used if starting values for model parameters are given with <code>emission_probs</code> ).
<code>emission_probs</code>	A matrix containing emission probabilities for each class by rows, or in case of multichannel data a list of such matrices. Note that the matrices must have dimensions $k \times s$ where $k$ is the number of latent classes and $s$ is the number of unique symbols (observed states) in the data. Emission probabilities should follow the ordering of the alphabet of observations ( <code>alphabet(observations)</code> , returned as <code>symbol_names</code> ).
<code>formula</code>	Optional formula of class <code>formula()</code> for the mixture probabilities. Left side omitted.
<code>data</code>	A data frame containing the variables used in the formula. Ignored if no formula is provided.
<code>coefficients</code>	An optional $k \times l$ matrix of regression coefficients for time-constant covariates for mixture probabilities, where $l$ is the number of clusters and $k$ is the number of covariates. A logit-link is used for mixture probabilities. The first column is set to zero.
<code>cluster_names</code>	A vector of optional names for the classes/clusters.
<code>channel_names</code>	A vector of optional names for the channels.

**Value**

Object of class `mhmm` with the following elements:

- `observations`  
State sequence object or a list of such containing the data.

- `transition_probs`  
A matrix of transition probabilities.
- `emission_probs`  
A matrix or a list of matrices of emission probabilities.
- `initial_probs`  
A vector of initial probabilities.
- `coefficients`  
A matrix of parameter coefficients for covariates (covariates in rows, clusters in columns).
- `X`  
Covariate values for each subject.
- `cluster_names`  
Names for clusters.
- `state_names`  
Names for hidden states.
- `symbol_names`  
Names for observed states.
- `channel_names`  
Names for channels of sequence data
- `length_of_sequences`  
(Maximum) length of sequences.
- `sequence_lengths`  
A vector of sequence lengths.
- `n_sequences`  
Number of sequences.
- `n_symbols`  
Number of observed states (in each channel).
- `n_states`  
Number of hidden states.
- `n_channels`  
Number of channels.
- `n_covariates`  
Number of covariates.
- `n_clusters`  
Number of clusters.

|-------------------------------|---|
| <code>observations</code>     | An <code>stslst</code> object (see <code>TraMineR::seqdef()</code> ) containing the sequences, or a list of such objects (one for each channel).  |
| <code>n_states</code>         | A numerical vector giving the number of hidden states in each submodel (not used if starting values for model parameters are given with <code>initial_probs</code> , <code>transition_probs</code> , or <code>emission_probs</code> ).  |
| <code>transition_probs</code> | A list of matrices of transition probabilities for the submodel of each cluster.  |
| <code>emission_probs</code>   | A list which contains matrices of emission probabilities or a list of such objects (one for each channel) for the submodel of each cluster. Note that the matrices must have dimensions $m \times s$ where $m$ is the number of hidden states and $s$ is the number of unique symbols (observed states) in the data. Emission probabilities should follow the ordering of the alphabet of observations ( <code>alphabet(observations)</code> , returned as <code>symbol_names</code> ). |
| <code>initial_probs</code>    | A list which contains vectors of initial state probabilities for the submodel of each cluster.  |
| <code>formula</code>          | Optional formula of class <code>formula()</code> for the mixture probabilities. Left side omitted.  |
| <code>data</code>             | A data frame containing the variables used in the formula. Ignored if no formula is provided.   |
| <code>coefficients</code>     | An optional $k \times l$ matrix of regression coefficients for time-constant covariates for mixture probabilities, where $l$ is the number of clusters and $k$ is the number of covariates. A logit-link is used for mixture probabilities. The first column is set to zero.  |
| <code>cluster_names</code>    | A vector of optional names for the clusters.  |

state_names	A list of optional labels for the hidden states. If NULL, the state names are taken as row names of transition matrices. If this is also NULL, numbered states are used.
channel_names	A vector of optional names for the channels.
...	Additional arguments to simulate_transition_probs.

### Details

The returned model contains some attributes such as `nobs` and `df`, which define the number of observations in the model and the number of estimable model parameters, used in computing BIC. When computing `nobs` for a multichannel model with  $C$  channels, each observed value in a single channel amounts to  $1/C$  observation, i.e. a fully observed time point for a single sequence amounts to one observation. For the degrees of freedom `df`, zero probabilities of the initial model are defined as structural zeroes.

### Value

Object of class `mhmm` with following elements:

- `observations`  
State sequence object or a list of such containing the data.
- `transition_probs`  
A matrix of transition probabilities.
- `emission_probs`  
A matrix or a list of matrices of emission probabilities.
- `initial_probs`  
A vector of initial probabilities.
- `coefficients`  
A matrix of parameter coefficients for covariates (covariates in rows, clusters in columns).
- `X`  
Covariate values for each subject.
- `cluster_names`  
Names for clusters.
- `state_names`  
Names for hidden states.
- `symbol_names`  
Names for observed states.
- `channel_names`  
Names for channels of sequence data
- `length_of_sequences`  
(Maximum) length of sequences.
- `sequence_lengths`  
A vector of sequence lengths.
- `n_sequences`  
Number of sequences.

- `n_symbols`  
Number of observed states (in each channel).
- `n_states`  
Number of hidden states.
- `n_channels`  
Number of channels.
- `n_covariates`  
Number of covariates.
- `n_clusters`  
Number of clusters.

---

`build_mm`*Build a Markov Model*

---

### Description

Function `build_mm()` builds and automatically estimates a Markov model. It is also a shortcut for constructing a Markov model as a restricted case of an `hmm` object.

### Usage

```
build_mm(observations)
```

### Arguments

`observations` An `stslst` object (see `TraMineR::seqdef()`) containing the sequences.

### Details

Unlike the other build functions in `seqHMM`, the `build_mm()` function automatically estimates the model parameters. In case of no missing values, initial and transition probabilities are directly estimated from the observed initial state probabilities and transition counts. In case of missing values, the EM algorithm is run once.

Note that it is possible that the data contains a symbol from which there are no transitions anywhere (even to itself), which would lead to a row in transition matrix full of zeros. In this case the `build_mm()` (as well as the EM algorithm) assumes that the the state is absorbing in a way that probability of staying in this state is 1.

### Value

Object of class `hmm` with following elements:

- `observations`  
State sequence object or a list of such containing the data.
- `transition_probs`  
A matrix of transition probabilities.
- `emission_probs`  
A matrix or a list of matrices of emission probabilities.
- `initial_probs`  
A vector of initial probabilities.
- `state_names`  
Names for hidden states.
- `symbol_names`  
Names for observed states.
- `channel_names`  
Names for channels of sequence data

- `length_of_sequences`  
(Maximum) length of sequences.
- `sequence_lengths`  
A vector of sequence lengths.
- `n_sequences`  
Number of sequences.
- `n_symbols`  
Number of observed states (in each channel).
- `n_states`  
Number of hidden states.
- `n_channels`  
Number of channels.

### See Also

[plot.hmm\(\)](#) for plotting the model.

### Examples

```
# Construct sequence data
data("mvad", package = "TraMineR")

mvad_alphabet <-
  c("employment", "FE", "HE", "joblessness", "school", "training")
mvad_labels <- c(
  "employment", "further education", "higher education",
  "joblessness", "school", "training"
)
mvad_scodes <- c("EM", "FE", "HE", "JL", "SC", "TR")
mvad_seq <- seqdef(mvad, 15:86,
  alphabet = mvad_alphabet,
  states = mvad_scodes, labels = mvad_labels, xtstep = 6,
  cpal = colorpalette[[6]]
)

# Estimate the Markov model
mm_mvad <- build_mm(observations = mvad_seq)
```

---

build\_mmm

*Build a Mixture Markov Model*

---

### Description

Function `build_mmm()` is a shortcut for constructing a mixture Markov model as a restricted case of an `mhmm` object.

**Usage**

```

build_mmm(
  observations,
  n_clusters,
  transition_probs,
  initial_probs,
  formula = NULL,
  data = NULL,
  coefficients = NULL,
  cluster_names = NULL,
  ...
)

```

**Arguments**

observations	An <code>stslist</code> object (see <code>TraMineR::seqdef()</code> ) containing the sequences.
n_clusters	A scalar giving the number of clusters/submodels (not used if starting values for model parameters are given with <code>initial_probs</code> and <code>transition_probs</code> ).
transition_probs	A list of matrices of transition probabilities for submodels of each cluster.
initial_probs	A list which contains vectors of initial state probabilities for submodels of each cluster.
formula	Optional formula of class <code>formula()</code> for the mixture probabilities. Left side omitted.
data	A data frame containing the variables used in the formula. Ignored if no formula is provided.
coefficients	An optional $k \times l$ matrix of regression coefficients for time-constant covariates for mixture probabilities, where $l$ is the number of clusters and $k$ is the number of covariates. A logit-link is used for mixture probabilities. The first column is set to zero.
cluster_names	A vector of optional names for the clusters.
...	Additional arguments to <code>simulate_transition_probs</code> .

**Value**

Object of class `mhmm` with following elements:

- `observations`  
State sequence object or a list of such containing the data.
- `transition_probs`  
A matrix of transition probabilities.
- `emission_probs`  
A matrix or a list of matrices of emission probabilities.
- `initial_probs`  
A vector of initial probabilities.

- `coefficients`  
A matrix of parameter coefficients for covariates (covariates in rows, clusters in columns).
- `X`  
Covariate values for each subject.
- `cluster_names`  
Names for clusters.
- `state_names`  
Names for hidden states.
- `symbol_names`  
Names for observed states.
- `channel_names`  
Names for channels of sequence data
- `length_of_sequences`  
(Maximum) length of sequences.
- `sequence_lengths`  
A vector of sequence lengths.
- `n_sequences`  
Number of sequences.
- `n_symbols`  
Number of observed states (in each channel).
- `n_states`  
Number of hidden states.
- `n_channels`  
Number of channels.
- `n_covariates`  
Number of covariates.
- `n_clusters`  
Number of clusters.

### Examples

```
# Define sequence data
data("mvad", package = "TraMineR")
mvad_alphabet <- c(
  "employment", "FE", "HE", "joblessness", "school",
  "training"
)
mvad_labels <- c(
  "employment", "further education", "higher education",
```

```

    "joblessness", "school", "training"
  )
  mvad_scodes <- c("EM", "FE", "HE", "JL", "SC", "TR")
  mvad_seq <- seqdef(mvad, 15:86,
    alphabet = mvad_alphabet, states = mvad_scodes,
    labels = mvad_labels, xtstep = 6
  )

  # Initialize the MMM
  set.seed(123)
  mmm_mvad <- build_mmm(
    observations = mvad_seq,
    n_clusters = 2,
    formula = ~male, data = mvad
  )

  ## Not run:
  # Estimate model parameters
  mmm_mvad <- fit_model(mmm_mvad)$model

  # Plot model (both clusters in the same plot)
  require(igraph)
  plot(mmm_mvad,
    interactive = FALSE,
    # Modify legend position and properties
    with.legend = "right", legend.prop = 0.3, cex.legend = 1.2,
    # Define vertex layout
    layout = layout_as_star,
    # Modify edge properties
    edge.label = NA, edge.arrow.size = 0.8, edge.curved = 0.2,
    # Modify vertex label positions (initial probabilities)
    vertex.label.pos = c("left", "right", "right", "left", "left", "right")
  )

  # Summary of the MMM
  summary(mmm_mvad)

  ## End(Not run)

```

---

cluster\_names

*Get Cluster Names from Mixture HMMs*

---

## Description

Get Cluster Names from Mixture HMMs

## Usage

```
cluster_names(object)
```

**Arguments**

object            An object of class mhmm or mnhmm.

**Value**

A character vector containing the cluster names.

---

cluster\_names<-            *Set Cluster Names for Mixture Models*

---

**Description**

Set Cluster Names for Mixture Models

**Usage**

```
cluster_names(object) <- value
```

**Arguments**

object            An object of class mhmm or mnhmm.  
value            A character vector containing the new cluster names.

**Value**

The modified object with updated cluster names.

---

coef.nhmm            *Get the Estimated Regression Coefficients of Non-Homogeneous Hidden Markov Models*

---

**Description**

Get the Estimated Regression Coefficients of Non-Homogeneous Hidden Markov Models

**Usage**

```
## S3 method for class 'nhmm'
coef(object, probs = NULL, ...)

## S3 method for class 'mnhmm'
coef(object, probs = NULL, ...)
```

**Arguments**

object	An object of class nhmm or mnhmm.
probs	Vector defining the quantiles of interest. When NULL (default), no quantiles are computed. The quantiles are based on bootstrap samples of coefficients, stored in object\$boot.
...	Ignored.

**Value**

A list of data tables with the estimated coefficients for initial, transition, emission (separate data table for each response), and cluster probabilities (in case of mixture model).

---

colorpalette	<i>Color palettes</i>
--------------	-----------------------

---

**Description**

A list containing ready defined color palettes with distinct colors using iWantHue. By default, seqHMM uses these palettes when assigning colors.

**Format**

A list with 200 color palettes.

**Source**

iWantHue web page <https://medialab.github.io/iwanthue/>

**See Also**

[plot\\_colors\(\)](#) for visualization of color palettes. Implementations of iWantHue for R:

- <https://github.com/hoesler/rwantshue>
- <https://github.com/johnbaums/hues>

**Examples**

```
data("colorpalette")
# Color palette with 9 colors
colorpalette[[9]]
# Color palette with 24 colors
colorpalette[[24]]
```

---

data_to_stslist	<i>Transform TraMineR's state sequence object to data.table and vice versa</i>
-----------------	--

---

### Description

Transform TraMineR's state sequence object to data.table and vice versa

### Usage

```
data_to_stslist(x, id, time, responses, seqdef_args = NULL, ...)
```

```
stslist_to_data(x, id, time, responses, ...)
```

### Arguments

x	For data_to_stslist, a data.frame type of object in long format, or a model object of class nhmm or mnhmm. For stslist_to_data, an object of class stslist or list of such objects.
id	A character string specifying the id variable. Ignored if x is NHMM.
time	A character string specifying the time variable. Ignored if x is NHMM.
responses	A character vector specifying the name(s) of the response variable(s). Ignored if x is NHMM.
seqdef_args	A list of additional arguments to <code>TraMineR::seqdef()</code> in case of data_to_stslist. In case of <code>length(responses) &gt; 1</code> , a list of lists. Ignored in stslist_to_data.
...	Ignored

---

estimate_mnhmm	<i>Estimate a Mixture Non-homogeneous Hidden Markov Model</i>
----------------	---

---

### Description

Function estimate\_mnhmm estimates a mixture version of non-homogeneous hidden Markov model (MNHMM) where initial, transition, emission, and mixture probabilities can depend on covariates. See `estimate_nhmm()` for further details.

### Usage

```
estimate_mnhmm(  
  n_states,  
  n_clusters,  
  emission_formula,  
  initial_formula = ~1,  
  transition_formula = ~1,
```

```

cluster_formula = ~1,
data,
time,
id,
lambda = 0,
prior_obs = "fixed",
state_names = NULL,
cluster_names = NULL,
inits = "random",
init_sd = 2,
restarts = 0L,
method = "EM-DNM",
bound = Inf,
control_restart = list(),
control_mstep = list(),
check_rank = NULL,
...
)

```

### Arguments

n_states	An integer > 1 defining the number of hidden states.
n_clusters	A positive integer defining the number of clusters (mixtures).
emission_formula	of class <code>formula()</code> for the state emission probabilities, or a list of such formulas in case of multiple response variables. The left-hand side of formulas define the responses. For multiple responses having same formula, you can use a form $c(y1, y2) \sim x$ , where $y1$ and $y2$ are the response variables.
initial_formula	of class <code>formula()</code> for the initial state probabilities. Left-hand side of the formula should be empty.
transition_formula	of class <code>formula()</code> for the state transition probabilities. Left-hand side of the formula should be empty.
cluster_formula	of class <code>formula()</code> for the mixture probabilities.
data	A data frame containing the variables used in the model formulas.
time	Name of the time index variable in data.
id	Name of the id variable in data identifying different sequences.
lambda	Penalization factor $\lambda$ for penalized log-likelihood, where the penalization is $0.5 * \lambda * \sum(\eta^2)$ . Note that with <code>method = "L-BFGS"</code> both objective function (log-likelihood) and the penalization term is scaled with number of non-missing observations. Default is 0, but small values such as $1e-4$ can help to ensure numerical stability of L-BFGS by avoiding extreme probabilities. See also argument <code>bound</code> for hard constraints.
prior_obs	Either "fixed" or a list of vectors given the prior distributions for the responses at time "zero". See details.

state_names	A vector of optional labels for the hidden states. If this is NULL (the default), numbered states are used.
cluster_names	A vector of optional labels for the clusters. If this is NULL (the default), numbered clusters are used.
inits	If inits = "random" (default), random initial values are used. Otherwise inits should be list of initial values. If coefficients are given using list components eta_pi, eta_A, eta_B, and eta_omega, these are used as is, alternatively initial values can be given in terms of the initial state, transition, emission, and mixture probabilities using list components initial_probs, emission_probs, transition_probs, and cluster_probs. These can also be mixed, i.e. you can give only initial_probs and eta_A.
init_sd	Standard deviation of the normal distribution used to generate random initial values. Default is 2. If you want to fix the initial values of the regression coefficients to zero, use init_sd = 0.
restarts	Number of times to run optimization using random starting values (in addition to the final run). Default is 0.
method	Optimization method used. Option "EM" uses EM algorithm with L-BFGS in the M-step. Option "DNM" uses direct maximization of the log-likelihood, by default using L-BFGS. Option "EM-DNM" (the default) runs first a maximum of 10 iterations of EM and then switches to L-BFGS (but other algorithms of NLOpt can be used).
bound	Positive value defining the hard lower and upper bounds for the working parameters $\eta$ , which are used to avoid extreme probabilities and corresponding numerical issues especially in the M-step of EM algorithm. Default is $\text{Inf}$ , i.e., no bounds. Note that he b = 0.
control_restart	Controls for restart steps, see details.
control_mstep	Controls for M-step of EM algorithm, see details.
check_rank	If TRUE, the rank of the design matrices are checked for identifiability issues. Default is NULL, in which case checks are performed only if the number of sequences is 1000 or less, as the QR decomposition quickly becomes computationally demanding. If check is not performed, a warning is given, which can be circumvented by explicitly using check_rank = FALSE.
...	Additional arguments to <code>nloptr::nloptr()</code> and EM algorithm. See details.

**Value**

Object of class `mnhmm`.

**See Also**

[estimate\\_nhmm\(\)](#) for further details.

**Examples**

```
data("mvad", package = "TraMineR")
```

```

d <- reshape(mvad, direction = "long", varying = list(15:86),
  v.names = "activity")

## Not run:
set.seed(1)
fit <- estimate_mnhmm(n_states = 3, n_clusters = 2,
  data = d, time = "time", id = "id",

  emission_formula = activity ~ male + catholic + gcse5eq,
  initial_formula = ~ 1,
  transition_formula = ~ male + gcse5eq
)

## End(Not run)

```

---

 estimate\_nhmm

*Estimate a Non-homogeneous Hidden Markov Model*

---

## Description

Function `estimate_nhmm` estimates a non-homogeneous hidden Markov model (NHMM) where initial, transition, and emission probabilities can depend on covariates. Transition and emission probabilities can also depend on past responses, in which case the model is called feedback-augmented NHMM (FAN-HMM) (Helske, 2025).

## Usage

```

estimate_nhmm(
  n_states,
  emission_formula,
  initial_formula = ~1,
  transition_formula = ~1,
  data,
  time,
  id,
  lambda = 0,
  prior_obs = "fixed",
  state_names = NULL,
  inits = "random",
  init_sd = 2,
  restarts = 0L,
  method = "EM-DNM",
  bound = Inf,
  control_restart = list(),
  control_mstep = list(),

```

```

    check_rank = NULL,
    ...
)

```

### Arguments

n_states	An integer > 1 defining the number of hidden states.
emission_formula	of class <code>formula()</code> for the state emission probabilities, or a list of such formulas in case of multiple response variables. The left-hand side of formulas define the responses. For multiple responses having same formula, you can use a form $c(y1, y2) \sim x$ , where $y1$ and $y2$ are the response variables.
initial_formula	of class <code>formula()</code> for the initial state probabilities. Left-hand side of the formula should be empty.
transition_formula	of class <code>formula()</code> for the state transition probabilities. Left-hand side of the formula should be empty.
data	A data frame containing the variables used in the model formulas.
time	Name of the time index variable in data.
id	Name of the id variable in data identifying different sequences.
lambda	Penalization factor $\lambda$ for penalized log-likelihood, where the penalization is $0.5 * \lambda * \sum(\eta^2)$ . Note that with <code>method = "L-BFGS"</code> both objective function (log-likelihood) and the penalization term is scaled with number of non-missing observations. Default is 0, but small values such as $1e-4$ can help to ensure numerical stability of L-BFGS by avoiding extreme probabilities. See also argument <code>bound</code> for hard constraints.
prior_obs	Either "fixed" or a list of vectors given the prior distributions for the responses at time "zero". See details.
state_names	A vector of optional labels for the hidden states. If this is NULL (the default), numbered states are used.
inits	If <code>inits = "random"</code> (default), random initial values are used. Otherwise <code>inits</code> should be list of initial values. If coefficients are given using list components <code>eta_pi</code> , <code>eta_A</code> , <code>eta_B</code> , these are used as is, alternatively initial values can be given in terms of the initial state, transition, and emission probabilities using list components <code>initial_probs</code> , <code>emission_probs</code> , and <code>transition_probs</code> . These can also be mixed, i.e. you can give only <code>initial_probs</code> and <code>eta_A</code> .
init_sd	Standard deviation of the normal distribution used to generate random initial values. Default is 2. If you want to fix the initial values of the regression coefficients to zero, use <code>init_sd = 0</code> .
restarts	Number of times to run optimization using random starting values (in addition to the final run). Default is 0.
method	Optimization method used. Option "EM" uses EM algorithm with L-BFGS in the M-step. Option "DNM" uses direct maximization of the log-likelihood, by default using L-BFGS. Option "EM-DNM" (the default) runs first a maximum of

	10 iterations of EM and then switches to L-BFGS (but other algorithms of NLOpt can be used).
bound	Positive value defining the hard lower and upper bounds for the working parameters $\eta$ , which are used to avoid extreme probabilities and corresponding numerical issues especially in the M-step of EM algorithm. Default is <code>Inf</code> , i.e., no bounds. Note that <code>bound = 0</code> .
control_restart	Controls for restart steps, see details.
control_mstep	Controls for M-step of EM algorithm, see details.
check_rank	If TRUE, the rank of the design matrices are checked for identifiability issues. Default is NULL, in which case checks are performed only if the number of sequences is 1000 or less, as the QR decomposition quickly becomes computationally demanding. If check is not performed, a warning is given, which can be circumvented by explicitly using <code>check_rank = FALSE</code> .
...	Additional arguments to <code>nloptr::nloptr()</code> and EM algorithm. See details.

## Details

In case of FAN-HMM with autoregressive dependency on the observational level, (i.e. response  $y_t$  depend on  $y_{t-1}$ ), the emission probabilities at the first time point need special attention. By default, the model is initialized with fixed values for the first time point (`prior_obs = "fixed"`), meaning that if the input data consists of time points  $t = 1, 2, \dots$ , then the model is defined from  $t = 2$  onward and the data on  $t = 1$  is used only for defining the emission probabilities at  $t = 2$ . Note that in this case also the initial state probabilities correspond to  $t = 2$ .

Alternatively, you can define `prior_obs` as a list of vectors, where the number of vectors is equal to the number of responses, and each vector gives the prior distribution for the response at  $t = 0$ . For example, if you have response variables `y` and `x`, where `y` has 3 categories and `x` 2 categories, you can define `prior_obs = list(y = c(0.5, 0.3, 0.2), x = c(0.7, 0.3))`. These distributions are then used to marginalize out  $y_0$  and  $x_0$  in the relevant emission probabilities.

By default, the model parameters are estimated using EM-DNM algorithm which first runs some iterations (100 by default) of EM algorithm, and then switches to L-BFGS. Other options include any numerical optimization algorithm of `nloptr::nloptr()`, or plain EM algorithm where the M-step uses L-BFGS (provided by the NLOpt library).

With multiple runs of optimization (by using the `restarts` argument), it is possible to parallelize these runs using the `future` package, e.g., by calling `future::plan(multisession, workers = 2)` before `estimate_nhmm()`. See `future::plan()` for details. This is compatible with `progressr` package, so you can use `progressr::with_progress()` to track the progress of these multiple runs.

During the estimation, the log-likelihood is scaled by the number of non-missing observations (`nobs(model)`), and the the covariate data is standardized before optimization.

By default, the convergence is claimed when the relative change of the objective function is less than  $1e-12$ , the absolute change is less than  $1e-8$  or the relative or absolute change of the working parameters `eta` is less than  $1e-6$ . These can be changed by passing arguments `ftol_rel`, `ftol_abs`, `xtol_rel`, and `xtol_abs` via `...`. These, as well as, `maxeval` (maximum number of iterations, 1e4 by default), and `print_level` (default is 0, no console output, larger values are more verbose), are used by the chosen main optimization method. The number of initial EM iterations in EM-DNM can

be set using argument `maxeval_em_dnm` (default is 100), and algorithm for direct numerical optimization can be defined using argument `algorithm` (see `nloptr::nloptr()` for possible options).

For controlling these stopping criteria for the multistart phase, argument `control_restart` takes a list such as `list(ftol_rel = 0.01, print_level = 1)`. Default are as in the case of main optimization (which is always run once after the restarts, using best solution from restarts as initial value) Additionally, same options can be defined separately for the M-step of EM algorithm via list `control_mstep`. For `control_mstep`, the default values are `ftol_rel = 1e-10`, and `maxeval = 1000`, and otherwise identical to previous defaults above.

## Value

Object of class `nhmm` or `fanhmm`.

---

fanhmm\_leaves

*A feedback-augmented non-homogeneous hidden Markov Model for leaves data*

---

## Description

A FAN-HMM fitted for theleaes data.

## Format

A model of class `fanhmm` with three hidden states

## Details

The model is loaded by calling `data(fanhmm_leaves)`. The code used to estimate the model is available on Github in `data-raw` folder.

## Examples

```
data("fanhmm_leaves")

fanhmm_leaves

get_marginals(fanhmm_leaves)
```

---

fit_model	<i>Estimate Parameters of (Mixture) Hidden Markov Models and Their Restricted Variants</i>
-----------	--

---

## Description

Function `fit_model` estimates the parameters of mixture hidden Markov models and its restricted variants using maximum likelihood. Initial values for estimation are taken from the corresponding components of the model with preservation of original zero probabilities.

## Usage

```
fit_model(  
  model,  
  em_step = TRUE,  
  global_step = FALSE,  
  local_step = FALSE,  
  control_em = list(),  
  control_global = list(),  
  control_local = list(),  
  lb,  
  ub,  
  threads = 1,  
  log_space = FALSE,  
  constraints = NULL,  
  fixed_inits = NULL,  
  fixed_emissions = NULL,  
  fixed_transitions = NULL,  
  ...  
)
```

**Arguments**

model	An object of class <code>hmm</code> or <code>mhmm</code> .
em_step	Logical. Whether or not to use the EM algorithm at the start of the parameter estimation. The default is <code>TRUE</code> .
global_step	Logical. Whether or not to use global optimization via <code>nloptr::nloptr()</code> (possibly after the EM step). The default is <code>FALSE</code> .
local_step	Logical. Whether or not to use local optimization via <code>nloptr::nloptr()</code> (possibly after the EM and/or global steps). The default is <code>FALSE</code> .
control_em	Optional list of control parameters for the EM algorithm. Possible arguments are <ul style="list-style-type: none"> <li>• <code>maxeval</code> The maximum number of iterations, the default is 1000. Note that iteration counter starts with -1 so with <code>maxeval = 1</code> you get already two iterations. This is for backward compatibility reasons.</li> <li>• <code>print_level</code> The level of printing. Possible values are 0 (prints nothing), 1 (prints information at the start and the end of the algorithm), 2 (prints at every iteration), and for mixture models 3 (print also during optimization of coefficients).</li> <li>• <code>reltol</code> Relative tolerance for convergence defined as <math>(\log Lik_{new} - \log Lik_{old}) / (\text{abs}(\log Lik_{old}) + 0.1)</math>. The default is <math>1e-10</math>.</li> <li>• <code>restart</code> A list containing options for possible EM restarts with the following components: <ul style="list-style-type: none"> <li>- <code>times</code> Number of restarts of the EM algorithm using random initial values. The default is 0, i.e. no restarts.</li> <li>- <code>transition</code> Logical. Should the original transition probabilities be varied? The default is <code>TRUE</code>.</li> <li>- <code>emission</code> Logical. Should the original emission probabilities be varied? The default is <code>TRUE</code>.</li> <li>- <code>sd</code> Standard deviation for <code>stats::rnorm()</code> used in randomization. The default is 0.25.</li> <li>- <code>maxeval</code> Maximum number of iterations, the default is <code>control_em\$maxeval</code></li> <li>- <code>print_level</code> Level of printing in restarted EM steps. The default is <code>control_em\$print_level</code>.</li> <li>- <code>reltol</code> Relative tolerance for convergence at restarted EM steps. The default is <code>control_em\$reltol</code>. If the relative change of the final model of the restart phase is larger than the tolerance for the original EM phase, the final model is re-estimated with the original <code>reltol</code> and <code>maxeval</code> at the end of the EM step.</li> </ul> </li> </ul>

	<ul style="list-style-type: none"> <li>- n_optimum Save the log-likelihood values of the n_optimum best models (from all estimated models including the the first EM run.). The default is min(times + 1, 25).</li> <li>- use_original If TRUE, use the initial values of the input model as starting points for the permutations. Otherwise permute the results of the first EM run.</li> </ul>
control_global	<p>Optional list of additional arguments for <code>nloptr::nloptr()</code> argument opts. The default values are</p> <ul style="list-style-type: none"> <li>• algorithm "NLOPT_GD_MLSL_LDS"</li> <li>• local_opts list(algorithm = "NLOPT_LD_LBFGS", ftol_rel = 1e-6, xtol_rel = 1e-4)</li> <li>• maxeval 10000 (maximum number of iterations in global optimization algorithm.)</li> <li>• maxtime 60 (maximum time for global optimization. Set to 0 for unlimited time.)</li> </ul>
control_local	<p>Optional list of additional arguments for <code>nloptr::nloptr()</code> argument opts. The default values are</p> <ul style="list-style-type: none"> <li>• algorithm "NLOPT_LD_LBFGS"</li> <li>• ftol_rel 1e-10</li> <li>• xtol_rel 1e-8</li> <li>• maxeval 10000 (maximum number of iterations)</li> </ul>
lb, ub	<p>Lower and upper bounds for parameters in Softmax parameterization. The default interval is <math>c(\text{pmin}(-25, 2 \times \text{initialvalues}), \text{pmax}(25, 2 \times \text{initialvalues}))</math>, except for gamma coefficients, where the scale of covariates is taken into account. Note that it might still be a good idea to scale covariates around unit scale. Bounds are used only in the global optimization step.</p>
threads	<p>Number of threads to use in parallel computing. The default is 1.</p>
log_space	<p>Make computations using log-space instead of scaling for greater numerical stability at a cost of decreased computational performance. The default is FALSE (but was TRUE in 2.0.0 version of the package).</p>
constraints	<p>Integer vector defining equality constraints for emission distributions. Not supported for EM algorithm. See details.</p>
fixed_inits	<p>Can be used to fix some of the probabilities to their initial values. Should have same structure as <code>model\$initial_probs</code>, where each element is either TRUE (fixed) or FALSE (to be estimated). Note that zero probabilities are always fixed to 0. Not supported for EM algorithm. See details.</p>
fixed_emissions	<p>Can be used to fix some of the probabilities to their initial values. Should have same structure as <code>model\$emission_probs</code>, where each element is either TRUE</p>

(fixed) or FALSE (to be estimated). Note that zero probabilities are always fixed to 0. Not supported for EM algorithm. See details.

`fixed_transitions` Can be used to fix some of the probabilities to their initial values. Should have same structure as `model$transition_probs`, where each element is either TRUE (fixed) or FALSE (to be estimated). Note that zero probabilities are always fixed to 0. Not supported for EM algorithm. See details.

... Additional arguments to `nloptr::nloptr()`.

## Details

The fitting function provides three estimation steps: 1) EM algorithm, 2) global optimization, and 3) local optimization. The user can call for one method or any combination of these steps, but should note that they are performed in the above-mentioned order. The results from a former step are used as starting values in a latter, except for some of global optimization algorithms (such as MLSL and StoGO) which only use initial values for setting up the boundaries for the optimization.

It is possible to rerun the EM algorithm automatically using random starting values based on the first run of EM. Number of restarts is defined by the `restart` argument in `control_em`. As the EM algorithm is relatively fast, this method might be preferred option compared to the proper global optimization strategy of step 2.

The default global optimization method (triggered via `global_step = TRUE`) is the multilevel single-linkage method (MLSL) with the LDS modification (`NLOPT_GD_MLSL_LDS` as `algorithm` in `control_global`), with L-BFGS as the local optimizer. The MLSL method draws random starting points and performs a local optimization from each. The LDS modification uses low-discrepancy sequences instead of pseudo-random numbers as starting points and should improve the convergence rate. In order to reduce the computation time spent on non-global optima, the convergence tolerance of the local optimizer is set relatively large. At step 3, a local optimization (L-BFGS by default) is run with a lower tolerance to find the optimum with high precision.

There are some theoretical guarantees that the MLSL method used as the default optimizer in step 2 should find all local optima in a finite number of local optimizations. Of course, it might not always succeed in a reasonable time. The EM algorithm can help in finding good boundaries for the search, especially with good starting values, but in some cases it can mislead. A good strategy is to try a couple of different fitting options with different combinations of the methods: e.g. all steps, only global and local steps, and a few evaluations of EM followed by global and local optimization.

By default, the estimation time is limited to 60 seconds in global optimization step, so it is advisable to change the default settings for the proper global optimization.

Any algorithm available in the `nloptr` function can be used for the global and local steps.

Equality constraints for emission distributions can be defined using the argument `constraints`. This should be a vector with length equal to the number of states, with numbers starting from 1 and increasing for each unique row of the emission probability matrix. For example in case of five states with emissions of first and third states being equal, `constraints = c(1, 2, 1, 3, 4)`. Similarly, some of the model parameters can be fixed to their initial values by using arguments `fixed_inits`, `fixed_emissions`, and `fixed_transitions`, where the structure of the arguments should be same as the corresponding model components, so that TRUE value means that the parameter should be fixed and FALSE otherwise (it is still treated as fixed if it is zero though). For both types of constrains, only numerical optimisation (local or global) is available, and currently the gradients are computed numerically (if needed) in these cases.

In a case where there is no transitions from one state to anywhere (even to itself), the state is defined as absorbing in a way that probability of staying in this state is fixed to 1. See also `build_mm` function.

### Value

- `logLik`  
Log-likelihood of the estimated model.
- `em_results`  
Results after the EM step: log-likelihood (`logLik`), number of iterations (`iterations`), relative change in log-likelihoods between the last two iterations (`change`), and the log-likelihoods of the `n_optimum` best models after the EM step (`best_opt_restart`).
- `global_results`  
Results after the global step.
- `local_results`  
Results after the local step.
- `call`  
The matched function call.

---

forward\_backward

*Forward and Backward Probabilities for Hidden Markov Model*

---

## Description

The `forward_backward` function computes forward and backward probabilities of a hidden Markov model.

## Usage

```

forward_backward(model, ...)

## S3 method for class 'hmm'
forward_backward(model, forward_only = FALSE, ...)

## S3 method for class 'mhmm'
forward_backward(model, forward_only = FALSE, ...)

## S3 method for class 'nhmm'
forward_backward(model, forward_only = FALSE, ...)

## S3 method for class 'mnhmm'
forward_backward(model, forward_only = FALSE, ...)

```

**Arguments**

model            A hidden Markov model.  
...              Ignored.  
forward\_only    If TRUE, only forward probabilities are computed. The default is FALSE.

**Value**

A data.frame with log-values of forward and backward probabilities.

**Examples**

```
# Load a pre-defined MHMM
data("mhmm_biofam")

# Compute forward and backward probabilities
fb <- forward_backward(mhmm_biofam)

head(fb)
```

---

get\_cluster\_probs            *Extract the Prior Cluster Probabilities of MHMM or MNHMM*

---

**Description**

Extract the Prior Cluster Probabilities of MHMM or MNHMM

**Usage**

```
get_cluster_probs(model)

## S3 method for class 'mnhmm'
get_cluster_probs(model)

## S3 method for class 'mhmm'
get_cluster_probs(model)
```

**Arguments**

model            A hidden Markov model.

**See Also**

[posterior\\_cluster\\_probabilities\(\)](#).

---

get\_emission\_probs      *Extract the Emission Probabilities of Hidden Markov Model*

---

**Description**

Extract the Emission Probabilities of Hidden Markov Model

**Usage**

```
get_emission_probs(model)

## S3 method for class 'nhmm'
get_emission_probs(model)

## S3 method for class 'mnhmm'
get_emission_probs(model)

## S3 method for class 'hmm'
get_emission_probs(model)

## S3 method for class 'mhmm'
get_emission_probs(model)
```

**Arguments**

model                  A hidden Markov model.

---

get\_initial\_probs      *Extract the Initial State Probabilities of Hidden Markov Model*

---

**Description**

Extract the Initial State Probabilities of Hidden Markov Model

**Usage**

```
get_initial_probs(model)

## S3 method for class 'nhmm'
get_initial_probs(model)

## S3 method for class 'mnhmm'
get_initial_probs(model)

## S3 method for class 'hmm'
```

```
get_initial_probs(model)

## S3 method for class 'mhmm'
get_initial_probs(model)
```

### Arguments

model            A hidden Markov model.

---

get\_marginals            *Compute the Marginal Probabilities from NHMMs*

---

### Description

get\_marginals returns the marginal state, response, transition, and emission probabilities, optionally per grouping defined by condition. By default, the marginalization weights sequences by the corresponding posterior probabilities of the latent states, i.e., conditional probabilities of the latent states given all data (weighting = "posterior"). If weighting = "forward", marginalization is based on forward probabilities, i.e. state probabilities given data up to that point which allows you to compute, for example, state marginals of form  $P(state_t | data_1, \dots, data_t)$  (whereas in posterior probability weighting the conditioning is on  $data_1, \dots, data_T$ ). If weighting = "none", all individuals and time points are treated equally, without accounting for the probability that individual is at particular state at particular time.

### Usage

```
get_marginals(
  model,
  probs = NULL,
  condition = NULL,
  newdata = NULL,
  type = c("state", "response", "transition", "emission"),
  weighting = c("posterior", "forward", "none")
)
```

### Arguments

model            An object of class nhmm or mnhmm.

probs            Vector defining the quantiles of interest. Default is NULL, in which case no quantiles are computed. The quantiles are based on bootstrap samples of coefficients, stored in object\$boot.

condition        An optional vector of variable names used for conditional marginal probabilities. Default is NULL, in which case marginalization is done over all variables, so that for example marginal emission probabilities are computed over all individuals and time points.

newdata         An optional data frame containing the new data to be used in computing the probabilities.

type	A character vector defining the marginal probabilities of interest. Can be one or multiple of "state", "response", "transition", and "emission". Default is to compute all of these.
weighting	A character string defining the type of weighting used in marginalization. One of "posterior", "forward", "none". See details.

---

get\_transition\_probs *Extract the State Transition Probabilities of Hidden Markov Model*

---

### Description

Extract the State Transition Probabilities of Hidden Markov Model

### Usage

```
get_transition_probs(model)

## S3 method for class 'nhmm'
get_transition_probs(model)

## S3 method for class 'mnhmm'
get_transition_probs(model)

## S3 method for class 'hmm'
get_transition_probs(model)

## S3 method for class 'mhmm'
get_transition_probs(model)
```

### Arguments

model            A hidden Markov model.

---

gridplot            *Plot Multidimensional Sequence Plots in a Grid*

---

### Description

Function gridplot plots multiple ssp objects to a grid.

**Usage**

```

gridplot(
  x,
  nrow = NA,
  ncol = NA,
  byrow = FALSE,
  with.legend = "auto",
  legend.pos = "auto",
  legend.pos2 = "center",
  title.legend = "auto",
  ncol.legend = "auto",
  with.missing.legend = "auto",
  row.prop = "auto",
  col.prop = "auto",
  cex.legend = 1
)

```

**Arguments**

x	A list of <code>ssp()</code> objects.
nrow, ncol	Optional arguments to arrange plots.
byrow	Controls the order of plotting. Defaults to FALSE, i.e. plots are arranged column-wise.
with.legend	Defines if and how the legends for the states are plotted. The default value "auto" (equivalent to TRUE and "many") creates separate legends for each requested plot. Other possibilities are "combined" (all legends combined) and FALSE (no legend).
legend.pos	Defines the positions of the legend boxes relative to the whole plot. Either one of "bottom" (equivalent to "auto") or "right", or a numerical vector of grid cells (by order) to print the legends to (the cells must be in one row/column).
legend.pos2	Defines the positions of the legend boxes relative to the cell(s). One of "bottomright", "bottom", "bottomleft", "left", "topleft", "top" (the default), "topright", "right" and "center".
title.legend	The titles for the legend boxes. The default "auto" takes the titles from the channel labels provided by the first object in x. NA prints no title.
ncol.legend	(A vector of) the number of columns for the legend(s). The default "auto" creates one column for each legend.
with.missing.legend	If set to "auto" (the default), a legend for the missing state is added automatically if one or more of the sequences in data contain missing states. With the value TRUE a legend for the missing state is added in any case; equivalently FALSE omits the legend for the missing state.
row.prop	Sets the proportions of the row heights of the grid. The default value is "auto" for even row heights. Takes a vector of values from 0 to 1, with values summing to 1.

col.prop	Sets the proportion of the column heights of the grid. The default value is "auto" for even column widths. Takes a vector of values from 0 to 1, with values summing to 1.
cex.legend	Expansion factor for setting the size of the font for the labels in the legend. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.

---

 hidden\_paths

*Most Probable Paths of Hidden States*

---

### Description

Function `hidden_paths` computes the most probable path of hidden states of a (mixture) hidden Markov model given the observed sequences.

### Usage

```
hidden_paths(model, ...)

## S3 method for class 'hmm'
hidden_paths(model, as_stslist = FALSE, ...)

## S3 method for class 'mhmm'
hidden_paths(model, as_stslist = FALSE, ...)

## S3 method for class 'nhmm'
hidden_paths(model, as_stslist = FALSE, ...)

## S3 method for class 'mnhmm'
hidden_paths(model, as_stslist = FALSE, ...)
```

### Arguments

model	A hidden Markov model.
...	Ignored.
as_stslist	Logical. If TRUE, the output is converted to an <code>stslist</code> object. Default is FALSE, which returns a <code>data.table</code> .

### Value

The most probable paths of hidden states as an `data.table`. The log-probability is included as an attribute `log_prop`.

### See Also

[hmm\\_biofam](#) for information on the model used in the example; and `ggseqplot::ggseqplot()` and `stacked_sequence_plot()` for plotting hidden paths.

**Examples**

```

# Load a pre-defined HMM
data("hmm_biofam")

# Compute the most probable hidden state paths given the data and the model
mpp <- hidden_paths(hmm_biofam)
head(mpp)
# Plot hidden paths for the first 100 individuals
seqs <- data_to_stslist(mpp, "id", "time", "state")
stacked_sequence_plot(seqs, type = "i", ids = 1:100)

# Because the model structure is so sparse that the posterior probabilities are
# mostly peaked to single state at each time point, the joint probability of
# observations and most probable paths of hidden states is almost identical to
# log-likelihood:

sum(attr(mpp, "log_prob"))
logLik(hmm_biofam)

```

---

hmm\_biofam

*Hidden Markov model for the biofam data*

---

**Description**

A five-state hidden Markov model (HMM) fitted for the `TraMineR::biofam()` data.

**Format**

A hidden Markov model of class `hmm`; a left-to-right model with four hidden states.

**Details**

The model is loaded by calling `data(hmm_biofam)`. It was created with the following code:

```

data("biofam3c")

# Building sequence objects
marr_seq <- seqdef(biofam3c$married,
  start = 15,
  alphabet = c("single", "married", "divorced"),
  cpal = c("violetred2", "darkgoldenrod2", "darkmagenta")
)
child_seq <- seqdef(biofam3c$children,
  start = 15,
  alphabet = c("childless", "children"),
  cpal = c("darkseagreen1", "coral3")
)

```

```

left_seq <- seqdef(biofam3c$left,
  start = 15,
  alphabet = c("with parents", "left home"),
  cpal = c("lightblue", "red3")
)

init <- c(0.9, 0.05, 0.02, 0.02, 0.01)

# Starting values for transition matrix
trans <- matrix(
  c(0.8, 0.10, 0.05, 0.03, 0.02,
    0, 0.9, 0.05, 0.03, 0.02,
    0, 0, 0.9, 0.07, 0.03,
    0, 0, 0, 0.9, 0.1,
    0, 0, 0, 0, 1),
  nrow = 5, ncol = 5, byrow = TRUE)

# Starting values for emission matrices
emiss_marr <- matrix(
  c(0.9, 0.05, 0.05, # High probability for single
    0.9, 0.05, 0.05,
    0.05, 0.9, 0.05, # High probability for married
    0.05, 0.9, 0.05,
    0.3, 0.3, 0.4), # mixed group
  nrow = 5, ncol = 3, byrow = TRUE)

emiss_child <- matrix(
  c(0.9, 0.1, # High probability for childless
    0.9, 0.1,
    0.1, 0.9,
    0.1, 0.9,
    0.5, 0.5),
  nrow = 5, ncol = 2, byrow = TRUE)

emiss_left <- matrix(
  c(0.9, 0.1, # High probability for living with parents
    0.1, 0.9,
    0.1, 0.9,
    0.1, 0.9,
    0.5, 0.5),
  nrow = 5, ncol = 2, byrow = TRUE)

initmod <- build_hmm(
  observations = list(marr_seq, child_seq, left_seq),
  initial_probs = init, transition_probs = trans,
  emission_probs = list(emiss_marr, emiss_child,
    emiss_left),
  channel_names = c("Marriage", "Parenthood", "Residence"))

```

```
fit_biofam <- fit_model(initmod, em = FALSE, local = TRUE)
hmm_biofam <- fit_biofam$model
```

---

hmm\_mvad

*Hidden Markov model for the mvad data*

---

### Description

A hidden Markov model (MMM) fitted for the `TraMineR::mvad()` data.

### Format

A hidden Markov model of class `hmm`; unrestricted model with six hidden states.

### Details

Model was created with the following code:

```
data("mvad", package = "TraMineR")

mvad_alphabet <-
  c("employment", "FE", "HE", "joblessness", "school", "training")
mvad_labels <- c("employment", "further education", "higher education",
  "joblessness", "school", "training")
mvad_scodes <- c("EM", "FE", "HE", "JL", "SC", "TR")
mvad_seq <- seqdef(mvad, 15:86, alphabet = mvad_alphabet,
  states = mvad_scodes, labels = mvad_labels, xtstep = 6,
  cpal = colorpalette[[6]])

# Starting values for the emission matrix
emiss <- matrix(
  c(0.05, 0.05, 0.05, 0.05, 0.75, 0.05, # SC
    0.05, 0.75, 0.05, 0.05, 0.05, 0.05, # FE
    0.05, 0.05, 0.05, 0.4, 0.05, 0.4, # JL, TR
    0.05, 0.05, 0.75, 0.05, 0.05, 0.05, # HE
```

```
      0.75, 0.05, 0.05, 0.05, 0.05, 0.05),# EM
      nrow = 5, ncol = 6, byrow = TRUE)

# Starting values for the transition matrix
trans <- matrix(0.025, 5, 5)
diag(trans) <- 0.9

# Starting values for initial state probabilities
initial_probs <- c(0.2, 0.2, 0.2, 0.2, 0.2)

# Building a hidden Markov model
init_hmm_mvad <- build_hmm(observations = mvad_seq,
  transition_probs = trans, emission_probs = emiss,
  initial_probs = initial_probs)

set.seed(21)
fit_hmm_mvad <- fit_model(init_hmm_mvad, control_em = list(restart = list(times = 100)))
hmm_mvad <- fit_hmm_mvad$model
```

plot(hmm_mvad)
```

---

leaves

*Synthetic data on fathers' parental leaves in Finland*

---

### Description

Synthetic data on fathers' parental leaves in Finland

### Format

A data.table with 9281 rows and 9 variables

### Details

The leaves data is a synthetic version of the Finnish fathers' leave-taking data used in Helske et al. (2024) and Helske (2025). The data consists of variables

- workplace: Workplace ID.
- father: father ID within workplace. More accurately, this is the birth of a child, i.e. same father can have multiple entries in data, but each entry has separate ID.
- year: Year when the child was born.
- leave: Factor of leave-taking of the father.
- Occupation: Factor of skill level of the father's occupation
- reform2013: Factor indicating whether the father was eligible for the leave under the 2013 reform.
- same\_occupation: Logical value, TRUE if father had same occupation as the previous father.
- lag\_reform2013: Factor indicating whether the previous father was eligible for the reform.
- lag\_occupation: Factor indicating the occupation of previous father.

---

logLik.hmm

*Log-likelihood of a Hidden Markov Model*

---

## Description

Log-likelihood of a Hidden Markov Model

## Usage

```
## S3 method for class 'hmm'
logLik(object, partials = FALSE, threads = 1, log_space = FALSE, ...)

## S3 method for class 'mhmm'
logLik(object, partials = FALSE, threads = 1, log_space = FALSE, ...)
```

**Arguments**

object	A hidden Markov model.
partials	Return a vector containing the individual contributions of each sequence to the total log-likelihood. The default is FALSE, which returns the sum of all log-likelihood components.
threads	Number of threads to use in parallel computing. The default is 1.
log_space	Make computations using log-space instead of scaling for greater numerical stability at the cost of decreased computational performance. The default is FALSE.
...	Ignored.

**Value**

Log-likelihood of the hidden Markov model. This is an object of class `logLik` with attributes `nobs` and `df` inherited from the model object.

---

logLik.nhmm	<i>Log-likelihood of a Non-homogeneous Hidden Markov Model</i>
-------------	--

---

**Description**

Log-likelihood of a Non-homogeneous Hidden Markov Model

**Usage**

```
## S3 method for class 'nhmm'
logLik(object, partials = FALSE, ...)

## S3 method for class 'mrnhmm'
logLik(object, partials = FALSE, ...)
```

**Arguments**

object	A hidden Markov model.
partials	Return a vector containing the individual contributions of each sequence to the total log-likelihood. The default is FALSE, which returns the sum of all log-likelihood components.
...	Ignored.

**Value**

Log-likelihood of the hidden Markov model. This is an object of class `logLik` with attributes `nobs` and `df` inherited from the model object.

---

mc_to_sc	<i>Transform a Multichannel Hidden Markov Model into a Single Channel Representation</i>
----------	--

---

### Description

Transforms data and parameters of a multichannel model into a single channel model. Observed states (symbols) are combined and parameters multiplied across channels.

### Usage

```
mc_to_sc(model, combine_missing = TRUE, all_combinations = FALSE, cpal)
```

### Arguments

model	An object of class <code>hmm</code> or <code>mhmm</code> .
combine_missing	Controls whether combined states of observations at time $t$ are coded missing (coded with <code>*</code> in <code>stslists</code> ) if one or more of the channels include missing information at time $t$ . Defaults to <code>TRUE</code> . <code>FALSE</code> keeps missing states as they are, producing more states in data; e.g. <code>single/childless/*</code> where the observation in channel 3 is missing.
all_combinations	Controls whether all possible combinations of observed states are included in the single channel representation or only combinations that are found in the data. Defaults to <code>FALSE</code> , i.e. only actual observations are included.
cpal	The color palette used for the new combined symbols. Optional in a case where the number of symbols is less or equal to 200 (in which case the <code>seqHMM::colorpalette</code> is used).

### Details

Note that in case of no missing observations, the log-likelihood of the original and transformed models are identical but the AIC and BIC can be different as the model attribute `df` is recomputed based on the single channel representation.

### See Also

[build\\_hmm\(\)](#) and [fit\\_model\(\)](#) for building and fitting Hidden Markov models; and [hmm\\_biofam\(\)](#) for information on the model used in the example.

### Examples

```
# Loading a hidden Markov model of the biofam data (hmm object)
data("hmm_biofam")

# Convert the multichannel model to a single-channel model
```

```

sc <- mc_to_sc(hmm_biofam)

# Likelihoods of the single-channel and the multichannel model are the same
# (Might not be true if there are missing observations)
logLik(sc)
logLik(hmm_biofam)

```

---

mc_to_sc_data	<i>Merge Multiple Sequence Objects into One (from Multichannel to Single Channel Data)</i>
---------------	--

---

## Description

Function `mc_to_sc_data` combines observed states of multiple sequence objects into one, time point by time point.

## Usage

```
mc_to_sc_data(data, combine_missing = TRUE, all_combinations = FALSE, cpal)
```

## Arguments

<code>data</code>	A list of state sequence objects ( <code>stslists</code> ) created with the <code>seqdef()</code> function.
<code>combine_missing</code>	Controls whether combined states of observations at time <code>t</code> are coded missing (coded with <code>*</code> in <code>stslists</code> ) if one or more of the channels include missing information at time <code>t</code> . Defaults to <code>TRUE</code> . <code>FALSE</code> keeps missing states as they are, producing more states in data; e.g. <code>single/childless/*</code> where the observation in channel 3 is missing.
<code>all_combinations</code>	Controls whether all possible combinations of observed states are included in the single channel representation or only combinations that are found in the data. Defaults to <code>FALSE</code> , i.e. only actual observations are included.
<code>cpal</code>	The color palette used for the new combined symbols. Optional in a case where the number of symbols is less or equal to 200 (in which case the <code>seqHMM:::colorpalette</code> is used).

## See Also

`mc_to_sc()` for transforming multichannel `hmm` or `mhmm` objects into single-channel representations; `stacked_sequence_plot` for plotting multiple sequence data sets in the same plot; and `seqdef()` for creating state sequence objects.

**Examples**

```

# Load three-channel sequence data
data("biofam3c")

# Building sequence objects
marr_seq <- seqdef(biofam3c$married,
  start = 15,
  alphabet = c("single", "married", "divorced"),
  cpal = c("violetred2", "darkgoldenrod2", "darkmagenta")
)
child_seq <- seqdef(biofam3c$children,
  start = 15,
  alphabet = c("childless", "children"),
  cpal = c("darkseagreen1", "coral3")
)
left_seq <- seqdef(biofam3c$left,
  start = 15,
  alphabet = c("with parents", "left home"),
  cpal = c("lightblue", "red3")
)

# Converting multichannel data to single-channel data
sc_data <- mc_to_sc_data(list(marr_seq, child_seq, left_seq))

# 10 combined states
alphabet(sc_data)

# Colors for combined states
attr(sc_data, "cpal") <- colorpalette[[14]][1:10]

# Plotting sequences for the first 10 subjects
stacked_sequence_plot(
  list(
    "Marriage" = marr_seq, "Parenthood" = child_seq,
    "Residence" = left_seq, "Combined" = sc_data
  ),
  type = "i",
  ids = 1:10
)

# Including all combinations (whether or not available in data)
sc_data_all <- mc_to_sc_data(list(marr_seq, child_seq, left_seq),
  all_combinations = TRUE
)

# 12 combined states, 2 with no observations in data
seqstatf(sc_data_all)

```

---

 mhmm\_biofam

*Mixture hidden Markov model for the biofam data*

---

## Description

A mixture hidden Markov model (MHMM) fitted for the `TraMineR::biofam()` data.

## Format

A mixture hidden Markov model of class `mhmm`: three clusters with left-to-right models including 4, 4, and 6 hidden states. Two covariates, `sex` and `cohort`, explaining the cluster membership.

## Details

The model was created with the following code:

```
data("biofam3c")

# Building sequence objects
marr_seq <- seqdef(biofam3c$married,
  start = 15,
  alphabet = c("single", "married", "divorced"),
  cpal = c("violetred2", "darkgoldenrod2", "darkmagenta")
)
child_seq <- seqdef(biofam3c$children,
  start = 15,
  alphabet = c("childless", "children"),
  cpal = c("darkseagreen1", "coral3")
)
left_seq <- seqdef(biofam3c$left,
  start = 15,
  alphabet = c("with parents", "left home"),
  cpal = c("lightblue", "red3")
)

### Examples

```

data("mhmm_biofam")

# use conditional_se = FALSE for more accurate standard errors
# (these are considerably slower to compute)
summary(mhmm_biofam$model)

if (interactive()) {
  # Plotting the model for each cluster (change with Enter)
  plot(mhmm_biofam)
}

```

---

mhmm\_mvad

*Mixture hidden Markov model for the mvad data*

---

### Description

A mixture hidden Markov model (MHMM) fitted for the `TraMineR::mvad()` data.

### Format

A mixture hidden Markov model of class `mhmm`: two clusters including 3 and 4 hidden states. No covariates.

### Details

The model is loaded by calling `data(mhmm_mvad)`. It was created with the following code:

```

data("mvad", package = "TraMineR")

mvad_alphabet <-
  c("employment", "FE", "HE", "joblessness", "school", "training")
mvad_labels <- c("employment", "further education", "higher education",
  "joblessness", "school", "training")
mvad_scodes <- c("EM", "FE", "HE", "JL", "SC", "TR")
mvad_seq <- seqdef(mvad, 15:86, alphabet = mvad_alphabet,

```

```

states = mvad_scodes, labels = mvad_labels, xstep = 6,
cpal = colorpalette[[6]])

# Starting values for the emission matrices
emiss_1 <- matrix(
  c(0.01, 0.01, 0.01, 0.01, 0.01, 0.95,
    0.95, 0.01, 0.01, 0.01, 0.01, 0.01,
    0.01, 0.01, 0.01, 0.95, 0.01, 0.01),
  nrow = 3, ncol = 6, byrow = TRUE)

emiss_2 <- matrix(
  c(0.01, 0.01, 0.01, 0.06, 0.90, 0.01,

---

most\_probable\_cluster *Extract Most Probable Cluster for Each Sequence*

---

**Description**

Extract Most Probable Cluster for Each Sequence

**Usage**

```
most_probable_cluster(x, type = "viterbi", hp = NULL)
```

**Arguments**

x	An object of class mhmm or mrhmm.
type	A character string specifying the method to use. Either "viterbi" (default) or "posterior". Former uses the most probable hidden path to determine the cluster membership for each sequence, while the latter finds the cluster which has the largest sum of posterior probabilities of states of that cluster.
hp	An output from <a href="#">hidden_paths()</a> function. Only used in case of type = "viterbi". If missing, hidden paths will be computed using x.

**Value**

A vector containing the most probable cluster for each sequence.

---

`mssplot`*Interactive Stacked Plots of Multichannel Sequences and/or Most Probable Paths for Mixture Hidden Markov Models*

---

**Description**

Function `mssplot` plots stacked sequence plots of observation sequences and/or most probable hidden state paths for each model of the `mhmm` object (model chosen according to the most probable path).

**Usage**

```
mssplot(  
  x,  
  ask = FALSE,  
  which.plots = NULL,  
  hidden.paths = NULL,  
  plots = "obs",  
  type = "d",  
  tlim = 0,  
  sortv = NULL,  
  sort.channel = 1,  
  dist.method = "OM",  
  with.missing = FALSE,  
  missing.color = NULL,  
  title = NA,  
  title.n = TRUE,  
  cex.title = 1,  
  title.pos = 1,  
  with.legend = "auto",  
  ncol.legend = "auto",  
  with.missing.legend = "auto",  
  legend.prop = 0.3,  
  cex.legend = 1,  
  hidden.states.colors = "auto",  
  hidden.states.labels = "auto",  
  xaxis = TRUE,  
  xlab = NA,  
  xtlab = NULL,  
  xlab.pos = 1,  
  ylab = "auto",  
  hidden.states.title = "Hidden states",  
  yaxis = FALSE,  
  ylab.pos = "auto",  
  cex.lab = 1,  
  cex.axis = 1,  
  respect_void = TRUE,
```

```
    ...
  )
```

### Arguments

<code>x</code>	Mixture hidden Markov model object of class <code>mhmm</code> .
<code>ask</code>	If TRUE and <code>which.plots</code> is NULL, <code>plot.mhmm</code> operates in interactive mode, via <code>menu()</code> . Defaults to FALSE.
<code>which.plots</code>	The number(s) of the requested model(s) as an integer vector. The default NULL produces all plots.
<code>hidden.paths</code>	Output from the <code>hidden_paths()</code> function. The default value NULL computes hidden paths automatically, if needed.
<code>plots</code>	What to plot. One of "obs" for observations (the default), "hidden.paths" for most probable paths of hidden states, or "both" for observations and hidden paths together.
<code>type</code>	The type of the plot. Available types are "I" for index plots and "d" for state distribution plots (the default). See <code>TraMineR::seqplot()</code> for details.
<code>tlim</code>	Indexes of the subjects to be plotted (the default is 0, i.e. all subjects are plotted). For example, <code>tlim = 1:10</code> plots the first ten subjects in data.
<code>sortv</code>	A sorting variable or a sort method (one of "from.start", "from.end", "mds.obs", or "mds.hidden") for <code>type = "I"</code> . The value "mds.hidden" is only available when <code>which = "both"</code> and <code>which = "hidden.paths"</code> . Options "mds.obs" and "mds.hidden" automatically arrange the sequences according to the scores of multidimensional scaling (using <code>stats::cmdscale()</code> ) for the observed data or hidden states paths. MDS scores are computed from distances/dissimilarities using a metric defined in argument <code>dist.method</code> . See <code>TraMineR::plot.stslist()</code> for more details on "from.start" and "from.end".
<code>sort.channel</code>	The number of the channel according to which the "from.start" or "from.end" sorting is done. Sorting according to hidden states is called with value 0. The default value is 1 (the first channel).
<code>dist.method</code>	The metric to be used for computing the distances of the sequences if multidimensional scaling is used for sorting. One of "OM" (optimal matching, the default), "LCP" (longest common prefix), "RLCP" (reversed LCP, i.e. longest common suffix), "LCS" (longest common subsequence), "HAM" (Hamming distance), and "DHD" (dynamic Hamming distance). Transition rates are used for defining substitution costs if needed. See <code>TraMineR::seqdef()</code> for more information on the metrics.
<code>with.missing</code>	Controls whether missing states are included in state distribution plots ( <code>type = "d"</code> ). The default is FALSE.
<code>missing.color</code>	Alternative color for representing missing values in the sequences. By default, this color is taken from the <code>missing.color</code> attribute of the sequence object.
<code>title</code>	A vector of main titles for the graphics. The default is NA: if <code>title.n = TRUE</code> , the name of the cluster and the number of subjects is plotted. FALSE prints no titles, even when <code>title.n = TRUE</code> .

<code>title.n</code>	Controls whether the number of subjects is printed in the main titles of the plots. The default is TRUE: <code>n</code> is plotted if <code>title</code> is anything but FALSE.
<code>cex.title</code>	Expansion factor for setting the size of the font for the main titles. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
<code>title.pos</code>	Controls the position of the main titles of the plots. The default value is 1. Values greater than 1 will place the title higher.
<code>with.legend</code>	Defines if and where the legend for the states is plotted. The default value "auto" (equivalent to TRUE and "right") creates separate legends for each requested plot and positions them on the right-hand side of the plot. Other possible values are "bottom", "right.combined", and "bottom.combined", of which the last two create a combined legend in the selected position. FALSE prints no legend.
<code>ncol.legend</code>	(A vector of) the number of columns for the legend(s). The default "auto" creates one column for each legend.
<code>with.missing.legend</code>	If set to "auto" (the default), a legend for the missing state is added automatically if one or more of the sequences in the data/channel contains missing states and <code>type = "I"</code> . If <code>type = "d"</code> missing states are omitted from the legends unless <code>with.missing = TRUE</code> . With the value TRUE a legend for the missing state is added in any case; equivalently FALSE omits the legend for the missing state.
<code>legend.prop</code>	Sets the proportion of the graphic area used for plotting the legend when <code>with.legend</code> is not FALSE. The default value is 0.3. Takes values from 0 to 1.
<code>cex.legend</code>	Expansion factor for setting the size of the font for the labels in the legend. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
<code>hidden.states.colors</code>	A vector of colors assigned to hidden states. The default value "auto" uses the colors assigned to the <code>stslst</code> object (created with <code>TraMineR::seqdef()</code> ) if <code>hidden.paths</code> is given; otherwise colors from <code>colorpalette()</code> are automatically used.
<code>hidden.states.labels</code>	Labels for the hidden states. The default value "auto" uses the names provided in <code>x\$state_names</code> if <code>x</code> is an <code>hmm</code> object; otherwise the number of the hidden state.
<code>xaxis</code>	Controls whether an x-axis is plotted below the plot at the bottom. The default value is TRUE.
<code>xlab</code>	An optional label for the x-axis. If set to NA, no label is drawn.
<code>xtlab</code>	Optional labels for the x-axis tick labels. If unspecified, the column names of the <code>seqdata</code> sequence object are used (see <code>TraMineR::seqdef()</code> ).
<code>xlab.pos</code>	Controls the position of the x-axis label. The default value is 1. Values greater than 1 will place the label further away from the plot.
<code>ylab</code>	Labels for the channels shown as labels for y-axes. A vector of names for each channel (observations). The default value "auto" uses the names provided in <code>x\$channel_names</code> if <code>x</code> is an <code>hmm</code> object; otherwise the names of the list in <code>x</code> if

	given, or the number of the channel if names are not given. FALSE prints no labels.
hidden.states.title	Optional label for the hidden state plot (in the y-axis). The default is "Hidden states".
yaxis	Controls whether or not to plot the y-axis. The default is FALSE.
ylab.pos	Controls the position of the y axis labels (labels for channels and/or hidden states). Either "auto" or a numerical vector indicating how far away from the plots the titles are positioned. The default value "auto" positions all titles on line 1. Shorter vectors are recycled.
cex.lab	Expansion factor for setting the size of the font for the axis labels. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
cex.axis	Expansion factor for setting the size of the font for the x-axis tick labels. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
respect_void	If TRUE (default), states at the time points corresponding to TraMineR's void in the observed sequences are set to void in the hidden state sequences as well.
...	Other arguments to be passed on to <code>TraMineR::seqplot()</code> .

**See Also**

`build_mhmm()` and `fit_model()` for building and fitting mixture hidden Markov models, `hidden_paths()` for computing the most probable paths (Viterbi paths) of hidden states, `plot.mhmm()` for plotting mhmm objects as directed graphs, and `colorpalette()` for default colors.

---

nobs.hmm

*Number of Observations in Hidden Markov Model*

---

**Description**

Extract the number of non-missing observations of HMM. When computing nobs for a multichannel model with  $C$  channels, each observed value in a single channel amounts to  $1/C$  observation, i.e. a fully observed time point for a single sequence amounts to one observation.

**Usage**

```
## S3 method for class 'hmm'
nobs(object, ...)

## S3 method for class 'mhmm'
nobs(object, ...)

## S3 method for class 'nhmm'
nobs(object, ...)

## S3 method for class 'mnhmm'
nobs(object, ...)
```

**Arguments**

object	An object of class hmm, mhmm, nhmm, or mnhmm.
...	Ignored.

---

permute_states	<i>Permute the states of NHMM using Hungarian algorithm</i>
----------------	---

---

**Description**

This function finds the permutation (according to Hungarian algorithm) of estimated model coefficients  $\gamma$  which best matches some reference values. The main purpose is to permute the bootstrap samples of model coefficients to match as closely as possible to the maximum likelihood estimates obtained from the original data.

**Usage**

```
permute_states(estimates, reference)
```

**Arguments**

estimates	A list $\gamma$ coefficients as in <code>model\$gammas</code> , where <code>model</code> is an <code>nhmm</code> object.
reference	Another list of $\gamma$ coefficients for which to match the estimates.

**Details**

The cost matrix in Hungarian algorithm is based on the sum of L2 norms of the differences of estimated and reference values of  $\pi$ ,  $A$  and  $B$ .

This function is mostly meant for internal usage within the bootstrap methods of `seqHMM`.

**Value**

Permuted version of `estimates`, with added attribute `permutation` which contains the permutations used to obtain for example the new `gamma_pi` as `estimates$gamma_pi[perm, , drop = FALSE]`.

---

`plot.hmm`*Plot hidden Markov models*

---

## Description

Function `plot.hmm` plots a directed graph with pie charts of emission probabilities as vertices/nodes.

## Usage

```
## S3 method for class 'hmm'
plot(
  x,
  layout = "horizontal",
  pie = TRUE,
  vertex.size = 40,
  vertex.label = "initial.probs",
  vertex.label.dist = "auto",
  vertex.label.pos = "bottom",
  vertex.label.family = "sans",
  loops = FALSE,
  edge.curved = TRUE,
  edge.label = "auto",
  edge.width = "auto",
  cex.edge.width = 1,
  edge.arrow.size = 1.5,
  edge.label.family = "sans",
  label.signif = 2,
  label.scientific = FALSE,
  label.max.length = 6,
  trim = 1e-15,
  combine.slices = 0.05,
  combined.slice.color = "white",
  combined.slice.label = "others",
  with.legend = "bottom",
  ltext = NULL,
  legend.prop = 0.5,
  cex.legend = 1,
  ncol.legend = "auto",
  cpal = "auto",
  cpal.legend = "auto",
  legend.order = TRUE,
  main = NULL,
  withlegend,
  ...
)
```

**Arguments**

x	A hidden Markov model object of class <code>hmm</code> created with <code>build_hmm()</code> (or <code>build_mm()</code> ). Multichannel <code>hmm</code> objects are automatically transformed into single-channel objects. See function <code>mc_to_sc()</code> for more information on the transformation.
layout	specifies the layout of vertices (nodes). Accepts a numerical matrix, a <code>igraph::layout_()</code> function (without quotation marks), or either of the predefined options "horizontal" (the default) and "vertical". Options "horizontal" and "vertical" position vertices at the same horizontal or vertical line. A two-column numerical matrix can be used to give x and y coordinates of the vertices. The <code>igraph::layout_()</code> functions available in the <code>igraph</code> package offer other automatic layouts for graphs.
pie	Are vertices plotted as pie charts of emission probabilities? Defaults to TRUE.
vertex.size	Size of vertices, given as a scalar or numerical vector. The default value is 40.
vertex.label	Labels for vertices. Possible options include "initial.probs", "names", NA, and a character or numerical vector. The default "initial.probs" prints the initial probabilities of the model and "names" prints the names of the hidden states as labels. NA prints no labels.
vertex.label.dist	Distance of the label of the vertex from its center. The default value "auto" places the label outside the vertex.
vertex.label.pos	Positions of vertex labels, relative to the center of the vertex. A scalar or numerical vector giving position(s) as radians or one of "bottom" ( $\pi/2$ as radians), "top" ( $-\pi/2$ ), "left" ( $\pi$ ), or "right" ( $0$ ).
vertex.label.family, edge.label.family	Font family to be used for vertex/edge labels. See argument family in <code>par()</code> for more information.
loops	Defines whether transitions back to same states are plotted.
edge.curved	Defines whether to plot curved edges (arcs, arrows) between vertices. A logical or numerical vector or scalar. Numerical values specify curvatures of edges. The default value TRUE gives curvature of 0.5 to all edges. See <code>igraph::igraph.plotting()</code> for more information.
edge.label	Labels for edges. Possible options include "auto", NA, and a character or numerical vector. The default "auto" prints transition probabilities as edge labels. NA prints no labels.
edge.width	Width(s) for edges. The default "auto" determines widths according to transition probabilities between hidden states. Other possibilities are a scalar or a numerical vector of widths.
cex.edge.width	An expansion factor for edge widths. Defaults to 1.
edge.arrow.size	Size of the arrow in edges (constant). Defaults to 1.5.
label.signif	Rounds labels of model parameters to specified number of significant digits, 2 by default. Ignored for user-given labels.

<code>label.scientific</code>	Defines if scientific notation should be used to describe small numbers. Defaults to FALSE, e.g. 0.0001 instead of 1e-04. Ignored for user-given labels.
<code>label.max.length</code>	Maximum number of digits in labels of model parameters. Ignored for user-given labels.
<code>trim</code>	Scalar between 0 and 1 giving the highest probability of transitions that are plotted as edges, defaults to 1e-15.
<code>combine.slices</code>	Scalar between 0 and 1 giving the highest probability of emission probabilities that are combined into one state. The default value is 0.05.
<code>combined.slice.color</code>	Color of the combined slice that includes the smallest emission probabilities (only if argument "combine.slices" is greater than 0). The default color is white.
<code>combined.slice.label</code>	The label for combined states (when argument "combine.slices" is greater than 0) to appear in the legend.
<code>with.legend</code>	Defines if and where the legend of state colors is plotted. Possible values include "bottom" (the default), "top", "left", and "right". FALSE omits the legend.
<code>ltext</code>	Optional description of (combined) observed states to appear in the legend. A vector of character strings. See <code>TraMineR::seqplot()</code> for more information.
<code>legend.prop</code>	Proportion used for plotting the legend. A scalar between 0 and 1, defaults to 0.5.
<code>cex.legend</code>	Expansion factor for setting the size of the font for labels in the legend. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
<code>ncol.legend</code>	The number of columns for the legend. The default value "auto" sets the number of columns automatically.
<code>cpal</code>	Optional color palette for (combinations of) observed states. The default value "auto" uses automatic color palette. Otherwise a vector of length $\times n_{\text{symbols}}$ is given, i.e. the argument requires a color specified for all (combinations of) observed states even if they are not plotted (if the probability is less than <code>combine.slices</code> ).
<code>cpal.legend</code>	Optional color palette for the legend, only considered when <code>legend.order</code> is FALSE. Should match <code>ltext</code> .
<code>legend.order</code>	Whether to use the default order in the legend, i.e., order by appearance (first by hidden state, then by emission probability). TRUE by default.
<code>main</code>	Main title for the plot. Omitted by default.
<code>withlegend</code>	Deprecated. Use <code>with.legend</code> instead.
<code>...</code>	Other parameters passed on to <code>igraph::plot.igraph()</code> such as <code>vertex.color</code> , <code>vertex.label.cex</code> , or <code>edge.lty</code> .

    withlegend,
    ...
)

```

## Arguments

x	A hidden Markov model object of class mhmm created with <code>build_mhmm()</code> (or <code>build_mmm()</code> or <code>build_lcm()</code> ). Multichannel mhmm objects are automatically transformed into single-channel objects. See function <code>mc_to_sc()</code> for more information on the transformation.
interactive	Whether to plot each cluster in succession or in a grid. Defaults to TRUE, i.e. clusters are plotted one after another.
ask	If TRUE and which.plots is NULL, plot.mhmm operates in interactive mode, via <code>utils::menu()</code> . Defaults to FALSE. Ignored if interactive = FALSE.
which.plots	The number(s) of the requested cluster(s) as an integer vector. The default NULL produces all plots.
nrow, ncol	Optional arguments to arrange plots in a grid. Ignored if interactive = TRUE.
byrow	Controls the order of plotting in a grid. Defaults to FALSE, i.e. plots are arranged column-wise. Ignored if interactive = TRUE.
row.prop	Sets the proportions of the row heights of the grid. The default value is "auto" for even row heights. Takes a vector of values from 0 to 1, with values summing to 1. Ignored if interactive = TRUE.
col.prop	Sets the proportion of the column heights of the grid. The default value is "auto" for even column widths. Takes a vector of values from 0 to 1, with values summing to 1. Ignored if interactive = TRUE.
layout	specifies the layout of vertices (nodes). Accepts a numerical matrix, a <code>igraph::layout_()</code> function (without quotation marks), or either of the predefined options "horizontal" (the default) and "vertical". Options "horizontal" and "vertical" position vertices at the same horizontal or vertical line. A two-column numerical matrix can be used to give x and y coordinates of the vertices. The <code>igraph::layout_()</code> functions available in the igraph package offer other automatic layouts for graphs.

pie	Are vertices plotted as pie charts of emission probabilities? Defaults to TRUE.
vertex.size	Size of vertices, given as a scalar or numerical vector. The default value is 40.
vertex.label	Labels for vertices. Possible options include "initial.probs", "names", NA, and a character or numerical vector. The default "initial.probs" prints the initial probabilities of the model and "names" prints the names of the hidden states as labels. NA prints no labels.
vertex.label.dist	Distance of the label of the vertex from its center. The default value "auto" places the label outside the vertex.
vertex.label.pos	Positions of vertex labels, relative to the center of the vertex. A scalar or numerical vector giving position(s) as radians or one of "bottom" ( $\pi/2$ as radians), "top" ( $-\pi/2$ ), "left" ( $\pi$ ), or "right" ( $0$ ).
vertex.label.family, edge.label.family	Font family to be used for vertex/edge labels. See argument family in <code>par()</code> for more information.
loops	Defines whether transitions back to same states are plotted.
edge.curved	Defines whether to plot curved edges (arcs, arrows) between vertices. A logical or numerical vector or scalar. Numerical values specify curvatures of edges. The default value TRUE gives curvature of 0.5 to all edges. See <code>igraph::igraph.plotting()</code> for more information.
edge.label	Labels for edges. Possible options include "auto", NA, and a character or numerical vector. The default "auto" prints transition probabilities as edge labels. NA prints no labels.
edge.width	Width(s) for edges. The default "auto" determines widths according to transition probabilities between hidden states. Other possibilities are a scalar or a numerical vector of widths.
cex.edge.width	An expansion factor for edge widths. Defaults to 1.
edge.arrow.size	Size of the arrow in edges (constant). Defaults to 1.5.
label.signif	Rounds labels of model parameters to specified number of significant digits, 2 by default. Ignored for user-given labels.
label.scientific	Defines if scientific notation should be used to describe small numbers. Defaults to FALSE, e.g. 0.0001 instead of $1e-04$ . Ignored for user-given labels.
label.max.length	Maximum number of digits in labels of model parameters. Ignored for user-given labels.
trim	Scalar between 0 and 1 giving the highest probability of transitions that are plotted as edges, defaults to $1e-15$ .
combine.slices	Scalar between 0 and 1 giving the highest probability of emission probabilities that are combined into one state. The default value is 0.05.
combined.slice.color	Color of the combined slice that includes the smallest emission probabilities (only if argument "combine.slices" is greater than 0). The default color is white.

<code>combined.slice.label</code>	The label for combined states (when argument <code>"combine.slices"</code> is greater than 0) to appear in the legend.
<code>with.legend</code>	Defines if and where the legend of state colors is plotted. Possible values include <code>"bottom"</code> (the default), <code>"top"</code> , <code>"left"</code> , and <code>"right"</code> . <code>FALSE</code> omits the legend.
<code>ltext</code>	Optional description of (combined) observed states to appear in the legend. A vector of character strings. See <code>TraMineR::seqplot()</code> for more information.
<code>legend.prop</code>	Proportion used for plotting the legend. A scalar between 0 and 1, defaults to 0.5.
<code>cex.legend</code>	Expansion factor for setting the size of the font for labels in the legend. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
<code>ncol.legend</code>	The number of columns for the legend. The default value <code>"auto"</code> sets the number of columns automatically.
<code>cpal</code>	Optional color palette for (combinations of) observed states. The default value <code>"auto"</code> uses automatic color palette. Otherwise a vector of length <code>x\$n_symbols</code> is given, i.e. the argument requires a color specified for all (combinations of) observed states even if they are not plotted (if the probability is less than <code>combine.slices</code> ).
<code>main</code>	Optional main titles for plots. The default <code>"auto"</code> uses <code>cluster_names</code> as titles, <code>NULL</code> prints no titles.
<code>withlegend</code>	Deprecated. Use <code>with.legend</code> instead.
<code>...</code>	Other parameters passed on to <code>igraph::plot.igraph()</code> such as <code>vertex.color</code> , <code>vertex.label.cex</code> , or <code>edge.lty</code> .

---

plot_colors	<i>Plot Colorpalettes</i>
-------------	---------------------------

---

**Description**

Function `plot_colors` plots colors and their labels for easy visualization of a colorpalette.

**Usage**

```
plot_colors(x, labels = NULL)
```

**Arguments**

`x` A vector of colors.  
`labels` A vector of labels for colors. If omitted, given color names are used.

**See Also**

See e.g. the [colorpalette\(\)](#) data and RColorBrewer package for ready-made color palettes.

**Examples**

```
plot_colors(colorpalette[[5]], labels = c("one", "two", "three", "four", "five"))  
plot_colors(colorpalette[[10]])  
plot_colors(1:7)  
plot_colors(c("yellow", "orange", "red", "purple", "blue", "green"))  
plot_colors(grDevices::rainbow(15))
```

---

posterior_cluster_probabilities	<i>Extract Posterior Cluster Probabilities</i>
---------------------------------	--

---

**Description**

Extract Posterior Cluster Probabilities

**Usage**

```
posterior_cluster_probabilities(x)
```

**Arguments**

`x` An object of class `mhmm` or `mnhmm`.

**Value**

a data.frame of posterior cluster probabilities for each sequence and cluster.

---

posterior_probs	<i>Posterior Probabilities for Hidden Markov Models</i>
-----------------	---

---

**Description**

Function posterior\_probs computes the posterior probabilities of hidden states of a (mixture) hidden Markov model.

**Usage**

```
posterior_probs(model, ...)

## S3 method for class 'hmm'
posterior_probs(model, ...)

## S3 method for class 'mhmm'
posterior_probs(model, ...)

## S3 method for class 'nhmm'
posterior_probs(model, ...)

## S3 method for class 'mnhmm'
posterior_probs(model, ...)
```

**Arguments**

model	A hidden Markov model object.
...	Ignored.

**Value**

A data frame of posterior probabilities for each state and sequence.

**Examples**

```
# Load a pre-defined MHMM
data("mhmm_biofam")

# Compute posterior probabilities
pb <- posterior_probs(mhmm_biofam)
```

**Description**

This function computes the marginal forward predictions for NHMMs and MNHMMs, where the marginalization is (by default) over individuals and time points, weighted by the latent state probabilities.

**Usage**

```
## S3 method for class 'nhmm'
predict(
  object,
  newdata,
  newdata2 = NULL,
  condition = NULL,
  type = c("state", "response", "transition", "emission"),
  probs = c(0.025, 0.975),
  boot_idx = FALSE,
  ...
)

## S3 method for class 'mnhmm'
predict(
  object,
  newdata,
  newdata2 = NULL,
  condition = NULL,
  type = c("state", "response", "transition", "emission"),
  probs = c(0.025, 0.975),
  boot_idx = FALSE,
  ...
)
```

**Arguments**

object	An object of class nhmm or mnhmm.
newdata	A data frame used for computing the predictions.
newdata2	An optional data frame for predictions, in which case the estimates are differences between predictions using newdata and newdata2.
condition	An optional vector of variable names used for conditional predictions.
type	A character vector defining the marginal predictions of interest. Can be one or multiple of "state", "response", "transition", and "emission". Default is to compute all of these.

probs	A numeric vector of quantiles to compute.
boot_idx	Logical indicating whether to use bootstrap samples in marginalization when computing quantiles. Default is FALSE. Currently only used in case where condition is NULL and
...	Ignored.

---

print.hmm                      *Print Method for a Hidden Markov Model*

---

### Description

Prints the parameters of a (mixture) hidden Markov model.

### Usage

```
## S3 method for class 'hmm'
print(x, digits = 3, ...)

## S3 method for class 'mhmm'
print(x, digits = 3, ...)

## S3 method for class 'nhmm'
print(x, digits = 3, ...)

## S3 method for class 'mnhmm'
print(x, digits = 3, ...)

## S3 method for class 'summary_mhmm'
print(x, digits = 3, ...)
```

### Arguments

x	Hidden Markov model.
digits	Minimum number of significant digits to print.
...	Further arguments to print.default.

### See Also

[build\\_hmm\(\)](#) and [fit\\_model\(\)](#) for building and fitting hidden Markov models.

---

return_msg	<i>Convert return code from estimate_nhmm and estimate_mnhmm to text</i>
------------	--

---

**Description**

Convert return code from estimate\_nhmm and estimate\_mnhmm to text

**Usage**

```
return_msg(code)
```

**Arguments**

code            Integer return code from model\$estimation\_results\$return\_code.

**Value**

Code translated to informative message.

---

separate_mhmm	<i>Reorganize a mixture hidden Markov model to a list of separate hidden Markov models (covariates ignored)</i>
---------------	---

---

**Description**

The separate\_mhmm function reorganizes the parameters of a mhmm object into a list where each list component is an object of class hmm consisting of the parameters of the corresponding cluster.

**Usage**

```
separate_mhmm(model)
```

**Arguments**

model            Mixture hidden Markov model of class mhmm.

**Value**

List with components of class hmm.

**See Also**

[build\\_mhmm\(\)](#) and [fit\\_model\(\)](#) for building and fitting MHMMs; and [mhmm\\_biofam\(\)](#) for more information on the model used in examples.

**Examples**

```
# Loading mixture hidden Markov model (mhmm object)
# of the biofam data
data("mhmm_biofam")

# Separate models for clusters
sep_hmm <- separate_mhmm(mhmm_biofam)

# Plotting the model for the first cluster
plot(sep_hmm[[1]])
```

---

seqHMM-deprecated      *Deprecated function(s) in the seqHMM package*

---

**Description**

These functions still work but will be removed (defunct) in the next version of seqHMM.

**Details**

- `ssplot`, `ssp`, `mssplot`, `plot.ssp`. Use `stacked_sequence_plot()` instead.
- `gridplot` Use `stacked_sequence_plot()`, `ggseqplot`, and `patchwork` packages instead.

---

simulate\_hmm      *Simulate hidden Markov models*

---

**Description**

Simulate sequences of observed and hidden states given parameters of a hidden Markov model.

**Usage**

```
simulate_hmm(
  n_sequences,
  initial_probs,
  transition_probs,
  emission_probs,
  sequence_length
)
```

**Arguments**

**n\_sequences**      The number of sequences to simulate.  
**initial\_probs**    A vector of initial state probabilities.  
**transition\_probs**  
                       A matrix of transition probabilities.  
**emission\_probs**   A matrix of emission probabilities or a list of such objects (one for each channel).  
**sequence\_length**  
                       Length for simulated sequences.

**Value**

A list of state sequence objects of class `stslst`.

**See Also**

[build\\_hmm\(\)](#) and [fit\\_model\(\)](#) for building and fitting hidden Markov models; [stacked\\_sequence\\_plot\(\)](#) for plotting multiple sequence data sets; [seqdef\(\)](#) for more information on state sequence objects; and [simulate\\_mhmm\(\)](#) for simulating mixture hidden Markov models.

**Examples**

```

# Parameters for the HMM
emission_probs <- matrix(c(0.5, 0.2, 0.5, 0.8), 2, 2)
transition_probs <- matrix(c(5 / 6, 1 / 6, 1 / 6, 5 / 6), 2, 2)
initial_probs <- c(1, 0)

# Setting the seed for simulation
set.seed(1)

# Simulating sequences
sim <- simulate_hmm(
  n_sequences = 10, initial_probs = initial_probs,
  transition_probs = transition_probs,
  emission_probs = emission_probs,
  sequence_length = 20
)

stacked_sequence_plot(sim, sort_by = "mds", type = "i")

```

---

simulate\_initial\_probs

*Simulate Parameters of Hidden Markov Models*

---

**Description**

These are helper functions for quick construction of initial values for various model building functions. Mostly useful for global optimization algorithms which do not depend on initial values.

**Usage**

```
simulate_initial_probs(n_states, n_clusters = 1, alpha = 1)

simulate_transition_probs(
  n_states,
  n_clusters = 1,
  left_right = FALSE,
  diag_c = 0,
  alpha = 1
)

simulate_emission_probs(n_states, n_symbols, n_clusters = 1, alpha = 1)
```

**Arguments**

n_states	Number of states in each cluster.
n_clusters	Number of clusters.
alpha	A scalar, or a vector of length S (number of states) or M (number of symbols) defining the parameters of the Dirichlet distribution used to simulate the probabilities.
left_right	Constrain the transition probabilities to upper triangular. Default is FALSE.
diag_c	A constant value to be added to diagonal of transition matrices before scaling.
n_symbols	Number of distinct symbols in each channel.

---

 simulate\_mhmm

*Simulate Mixture Hidden Markov Models*

---

**Description**

Simulate sequences of observed and hidden states given the parameters of a mixture hidden Markov model.

**Usage**

```
simulate_mhmm(
  n_sequences,
  initial_probs,
  transition_probs,
  emission_probs,
  sequence_length,
  formula = NULL,
  data = NULL,
  coefficients = NULL
)
```

**Arguments**

n_sequences	The number of sequences to simulate.
initial_probs	A list containing vectors of initial state probabilities for the submodel of each cluster.
transition_probs	A list of matrices of transition probabilities for the submodel of each cluster.
emission_probs	A list which contains matrices of emission probabilities or a list of such objects (one for each channel) for the submodel of each cluster. Note that the matrices must have dimensions $s \times m$ where $s$ is the number of hidden states and $m$ is the number of unique symbols (observed states) in the data.
sequence_length	The length of the simulated sequences.
formula	Covariates as an object of class <code>formula()</code> , left side omitted.
data	An optional data frame, a list or an environment containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> .
coefficients	An optional $k \times l$ matrix of regression coefficients for time-constant covariates for mixture probabilities, where $l$ is the number of clusters and $k$ is the number of covariates. A logit-link is used for mixture probabilities. The first column is set to zero.

**Value**

A list of state sequence objects of class `stslst`.

**See Also**

`build_mhmm()` and `fit_model()` for building and fitting mixture hidden Markov models.

**Examples**

```

emission_probs_1 <- matrix(c(0.75, 0.05, 0.25, 0.95), 2, 2)
emission_probs_2 <- matrix(c(0.1, 0.8, 0.9, 0.2), 2, 2)
colnames(emission_probs_1) <- colnames(emission_probs_2) <-
  c("heads", "tails")

transition_probs_1 <- matrix(c(9, 0.1, 1, 9.9) / 10, 2, 2)
transition_probs_2 <- matrix(c(35, 1, 1, 35) / 36, 2, 2)
rownames(emission_probs_1) <- rownames(transition_probs_1) <-
  colnames(transition_probs_1) <- c("coin 1", "coin 2")
rownames(emission_probs_2) <- rownames(transition_probs_2) <-
  colnames(transition_probs_2) <- c("coin 3", "coin 4")

initial_probs_1 <- c(1, 0)
initial_probs_2 <- c(1, 0)

n <- 30
set.seed(123)
covariate_1 <- runif(n)

```

```

covariate_2 <- sample(c("A", "B"),
  size = n, replace = TRUE,
  prob = c(0.3, 0.7)
)
dataf <- data.frame(covariate_1, covariate_2)

coefs <- cbind(cluster_1 = c(0, 0, 0), cluster_2 = c(-1.5, 3, -0.7))
rownames(coefs) <- c("(Intercept)", "covariate_1", "covariate_2B")

sim <- simulate_mhmm(
  n = n, initial_probs = list(initial_probs_1, initial_probs_2),
  transition_probs = list(transition_probs_1, transition_probs_2),
  emission_probs = list(emission_probs_1, emission_probs_2),
  sequence_length = 20, formula = ~ covariate_1 + covariate_2,
  data = dataf, coefficients = coefs
)

stacked_sequence_plot(sim,
  sort_by = "start", sort_channel = "states", type = "i"
)

hmm <- build_mhmm(sim$observations,
  initial_probs = list(initial_probs_1, initial_probs_2),
  transition_probs = list(transition_probs_1, transition_probs_2),
  emission_probs = list(emission_probs_1, emission_probs_2),
  formula = ~ covariate_1 + covariate_2,
  data = dataf
)

fit <- fit_model(hmm)
fit$model

paths <- hidden_paths(fit$model, as_stslist = TRUE)

stacked_sequence_plot(
  list(
    "estimated paths" = paths,
    "true (simulated)" = sim$states
  ),
  sort_by = "start",
  sort_channel = "true (simulated)",
  type = "i"
)

```

**Description**

Simulate sequences of observed and hidden states given the parameters of a mixture non-homogeneous hidden Markov model.

**Usage**

```
simulate_mnhmm(
  n_states,
  n_clusters,
  emission_formula,
  initial_formula = ~1,
  transition_formula = ~1,
  cluster_formula = ~1,
  data,
  id,
  time,
  coefs = NULL,
  init_sd = 2 * is.null(coefs),
  check_rank = NULL
)
```

**Arguments**

**n\_states** An integer > 1 defining the number of hidden states.

**n\_clusters** The number of clusters/mixtures.

**emission\_formula** of class `formula()` for the state emission probabilities, or a list of such formulas in case of multiple response variables. The left-hand side of formulas define the responses. For multiple responses having same formula, you can use a form  $c(y1, y2) \sim x$ , where  $y1$  and  $y2$  are the response variables.

**initial\_formula** of class `formula()` for the initial state probabilities. Left-hand side of the formula should be empty.

**transition\_formula** of class `formula()` for the state transition probabilities. Left-hand side of the formula should be empty.

**cluster\_formula** of class `formula()` for the mixture probabilities.

**data** A data frame containing the variables used in the model formulas. Note that this should also include also the response variable(s), which are used to define the number of observed symbols (using `levels()`) and the length of sequences. The actual values of the response variables does not matter though, as they are replaced by the simulated values. The exception is the first time point in FAN-HMM case: If the `emission_formula` contains lagged responses, the response variable values at the first time point are used to define the emissions at the second time point, and the simulations are done from the second time point onward. This matches the case `prior_obs = "fixed"` in `estimate_nhmm()`. Note that

compared to `estimate_*` functions, unused factor levels are not automatically dropped from data.

<code>id</code>	Name of the id variable in data identifying different sequences.
<code>time</code>	Name of the time index variable in data.
<code>coefs</code>	Same as argument <code>inits</code> in <code>estimate_mnhmm()</code> . If NULL, (default), the model parameters are generated randomly. If you want to simulate new sequences based on an estimated model fit, you can use <code>coefs = fit\$etas</code> and <code>init_sd = 0</code> .
<code>init_sd</code>	Standard deviation of the normal distribution used to generate random coefficients. Default is 2 when <code>coefs</code> is NULL and 0 otherwise.
<code>check_rank</code>	If TRUE, the rank of the design matrices are checked for identifiability issues. Default is NULL, in which case checks are performed only if the number of sequences is 1000 or less, as the QR decomposition quickly becomes computationally demanding. If check is not performed, a warning is given, which can be circumvented by explicitly using <code>check_rank = FALSE</code> .

**Value**

A list with the model used in simulation as well as the simulated hidden state sequences.

---

simulate\_nhmm

*Simulate Non-homogeneous Hidden Markov Models*

---

**Description**

Simulate sequences of observed and hidden states given the parameters of a non-homogeneous hidden Markov model.

**Usage**

```
simulate_nhmm(
  n_states,
  emission_formula,
  initial_formula = ~1,
  transition_formula = ~1,
  data,
  id,
  time,
  coefs = NULL,
  init_sd = 2 * is.null(coefs),
  check_rank = NULL
)
```

**Arguments**

n_states	An integer > 1 defining the number of hidden states.
emission_formula	of class <code>formula()</code> for the state emission probabilities, or a list of such formulas in case of multiple response variables. The left-hand side of formulas define the responses. For multiple responses having same formula, you can use a form $c(y1, y2) \sim x$ , where $y1$ and $y2$ are the response variables.
initial_formula	of class <code>formula()</code> for the initial state probabilities. Left-hand side of the formula should be empty.
transition_formula	of class <code>formula()</code> for the state transition probabilities. Left-hand side of the formula should be empty.
data	A data frame containing the variables used in the model formulas. Note that this should also include also the response variable(s), which are used to define the number of observed symbols (using <code>levels()</code> ) and the length of sequences. The actual values of the response variables does not matter though, as they are replaced by the simulated values. The exception is the first time point in FAN-HMM case: If the <code>emission_formula</code> contains lagged responses, the response variable values at the first time point are used to define the emissions at the second time point, and the simulations are done from the second time point onward. This matches the case <code>prior_obs = "fixed"</code> in <code>estimate_nhmm()</code> . Note that compared to <code>estimate_*</code> functions, unused factor levels are not automatically dropped from data.
id	Name of the id variable in data identifying different sequences.
time	Name of the time index variable in data.
coefs	Same as argument <code>inits</code> in <code>estimate_nhmm()</code> . If NULL, (default), the model parameters are generated randomly. If you want to simulate new sequences based on an estimated model fit, you can use <code>coefs = fit\$etas</code> and <code>init_sd = 0</code> .
init_sd	Standard deviation of the normal distribution used to generate random coefficients. Default is 2 when <code>coefs</code> is NULL and 0 otherwise.
check_rank	If TRUE, the rank of the design matrices are checked for identifiability issues. Default is NULL, in which case checks are performed only if the number of sequences is 1000 or less, as the QR decomposition quickly becomes computationally demanding. If check is not performed, a warning is given, which can be circumvented by explicitly using <code>check_rank = FALSE</code> .

**Value**

A list with the model used in simulation as well as the simulated hidden state sequences.

---

sort_sequences	<i>Sort sequences in a sequence object</i>
----------------	--

---

### Description

Sort sequences in a sequence object

### Usage

```
sort_sequences(x, sort_by = "start", sort_channel = 1, dist_method = "OM")
```

### Arguments

x	An <code>stslis</code> t object or a list of of such objects of same size, typically created with <code>TraMineR::seqdef()</code> or <code>data_to_stslis</code> t().
sort_by	A character string specifying the sorting criterion. Options are "none" (no sorting), "start" (sort by the first state), "end" (sort by last state), and "mds" (sort by the multidimensional scaling).
sort_channel	An integer or character string specifying the channel to sort by (unless <code>sort_by = "mds"</code> in which case all channels are used for defining the sorting).
dist_method	A character string specifying the distance method to use when sorting by the multidimensional scaling. Passed to <code>TraMineR::seqdist()</code> , or <code>TraMineR::seqMD()</code> in the multichannel case.

---

ssp	<i>Define Arguments for Plotting Multichannel Sequences and/or Most Probable Paths from Hidden Markov Models</i>
-----	--

---

### Description

Function `ssp` defines the arguments for plotting with `plot.ssp()` or `gridplot()`.

### Usage

```
ssp(
  x,
  hidden.paths = NULL,
  plots = "obs",
  type = "d",
  tlim = 0,
  sortv = NULL,
  sort.channel = 1,
  dist.method = "OM",
  with.missing = FALSE,
```

```

missing.color = NULL,
title = NA,
title.n = TRUE,
cex.title = 1,
title.pos = 1,
with.legend = "auto",
ncol.legend = "auto",
with.missing.legend = "auto",
legend.prop = 0.3,
cex.legend = 1,
hidden.states.colors = "auto",
hidden.states.labels = "auto",
xaxis = TRUE,
xlab = NA,
xtlab = NULL,
xlab.pos = 1,
ylab = "auto",
hidden.states.title = "Hidden states",
yaxis = FALSE,
ylab.pos = "auto",
cex.lab = 1,
cex.axis = 1,
withlegend,
respect_void = TRUE,
...
)

```

### Arguments

x	Either a hidden Markov model object of class <code>hmm</code> or a state sequence object of class <code>stslist</code> (created with the <code>TraMineR::seqdef()</code> function) or a list of state sequence objects.
hidden.paths	Output from <code>hidden_paths()</code> function. Optional, if <code>x</code> is a <code>hmm</code> object or if <code>type = "obs"</code> .
plots	What to plot. One of <code>"obs"</code> for observations (the default), <code>"hidden.paths"</code> for most probable paths of hidden states, or <code>"both"</code> for observations and hidden paths together.
type	The type of the plot. Available types are <code>"I"</code> for sequence index plots and <code>"d"</code> for state distribution plots (the default). See <code>TraMineR::seqplot()</code> for details.
tlim	Indexes of the subjects to be plotted (the default is 0, i.e. all subjects are plotted). For example, <code>tlim = 1:10</code> plots the first ten subjects in data.
sortv	A sorting variable or a sort method (one of <code>"from.start"</code> , <code>"from.end"</code> , <code>"mds.obs"</code> , or <code>"mds.hidden"</code> ) for <code>type = "I"</code> . The value <code>"mds.hidden"</code> is only available when hidden paths are available. Options <code>"mds.obs"</code> and <code>"mds.hidden"</code> automatically arrange the sequences according to the scores of multidimensional scaling (using <code>stats::cmdscale()</code> ) for the observed data or hidden states paths. MDS scores are computed from distances/dissimilarities using a metric defined

	in argument <code>dist.method</code> . See <code>TraMineR::plot.stslist()</code> for more details on <code>"from.start"</code> and <code>"from.end"</code> .
<code>sort.channel</code>	The number of the channel according to which the <code>"from.start"</code> or <code>"from.end"</code> sorting is done. Sorting according to hidden states is called with value 0. The default value is 1 (the first channel).
<code>dist.method</code>	The metric to be used for computing the distances of the sequences if multi-dimensional scaling is used for sorting. One of "OM" (optimal matching, the default), "LCP" (longest common prefix), "RLCP" (reversed LCP, i.e. longest common suffix), "LCS" (longest common subsequence), "HAM" (Hamming distance), and "DHD" (dynamic Hamming distance). Transition rates are used for defining substitution costs if needed. See <code>TraMineR::seqdef()</code> for more information on the metrics.
<code>with.missing</code>	Controls whether missing states are included in state distribution plots ( <code>type = "d"</code> ). The default is FALSE.
<code>missing.color</code>	Alternative color for representing missing values in the sequences. By default, this color is taken from the <code>missing.color</code> attribute of the sequence object.
<code>title</code>	Main title for the graphic. The default is NA: if <code>title.n = TRUE</code> , only the number of subjects is plotted. FALSE prints no title, even when <code>title.n = TRUE</code> .
<code>title.n</code>	Controls whether the number of subjects (in the first channel) is printed in the title of the plot. The default is TRUE: n is plotted if <code>title</code> is anything but FALSE.
<code>cex.title</code>	Expansion factor for setting the size of the font for the title. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
<code>title.pos</code>	Controls the position of the main title of the plot. The default value is 1. Values greater than 1 will place the title higher.
<code>with.legend</code>	Defines if and where the legend for the states is plotted. The default value "auto" (equivalent to TRUE and "right") creates separate legends for each requested plot and positions them on the right-hand side of the plot. Other possible values are "bottom", "right.combined", and "bottom.combined", of which the last two create a combined legend in the selected position. FALSE prints no legend.
<code>ncol.legend</code>	(A vector of) the number of columns for the legend(s). The default "auto" determines number of columns depending on the position of the legend.
<code>with.missing.legend</code>	If set to "auto" (the default), a legend for the missing state is added automatically if one or more of the sequences in the data/channel contains missing states and <code>type = "I"</code> . If <code>type = "d"</code> missing states are omitted from the legends unless <code>with.missing = TRUE</code> . With the value TRUE a legend for the missing state is added in any case; equivalently FALSE omits the legend for the missing state.
<code>legend.prop</code>	Sets the proportion of the graphic area used for plotting the legend when <code>with.legend</code> is not FALSE. The default value is 0.3. Takes values from 0 to 1.
<code>cex.legend</code>	Expansion factor for setting the size of the font for the labels in the legend. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.

<code>hidden.states.colors</code>	A vector of colors assigned to hidden states. The default value "auto" uses the colors assigned to the <code>stslst</code> object (created with <code>TraMineR::seqdef()</code> ) if <code>hidden.paths</code> is given; otherwise colors from <code>colorpalette()</code> are automatically used.
<code>hidden.states.labels</code>	Labels for the hidden states. The default value "auto" uses the names provided in <code>x\$state_names</code> if <code>x</code> is an <code>hmm</code> object; otherwise the number of the hidden state.
<code>xaxis</code>	Controls whether an x-axis is plotted below the plot at the bottom. The default value is <code>TRUE</code> .
<code>xlab</code>	An optional label for the x-axis. If set to <code>NA</code> , no label is drawn.
<code>xtlab</code>	Optional labels for the x-axis tick labels. If unspecified, the column names of the <code>seqdata</code> sequence object are used (see <code>TraMineR::seqdef()</code> ).
<code>xlab.pos</code>	Controls the position of the x-axis label. The default value is 1. Values greater than 1 will place the label further away from the plot.
<code>ylab</code>	Labels for the channels shown as labels for y-axes. A vector of names for each channel (observations). The default value "auto" uses the names provided in <code>x\$channel_names</code> if <code>x</code> is an <code>hmm</code> object; otherwise the names of the list in <code>x</code> if given, or the number of the channel if names are not given. <code>FALSE</code> prints no labels.
<code>hidden.states.title</code>	Optional label for the hidden state plot (in the y-axis). The default is "Hidden states".
<code>yaxis</code>	Controls whether or not to plot the y-axis. The default is <code>FALSE</code> .
<code>ylab.pos</code>	Controls the position of the y axis labels (labels for channels and/or hidden states). Either "auto" or a numerical vector indicating how far away from the plots the titles are positioned. The default value "auto" positions all titles on line 1. Shorter vectors are recycled.
<code>cex.lab</code>	Expansion factor for setting the size of the font for the axis labels. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
<code>cex.axis</code>	Expansion factor for setting the size of the font for the x-axis tick labels. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
<code>withlegend</code>	Deprecated. Use <code>with.legend</code> instead.
<code>respect_void</code>	If <code>TRUE</code> (default), states at the time points corresponding to TraMineR's void in the observed sequences are set to void in the hidden state sequences as well.
<code>...</code>	Other arguments to be passed on to <code>TraMineR::seqplot()</code> .

## Details

This function is deprecated, use `stacked_sequence_plot()` instead.

## Value

Object of class `ssp`.

---

`ssplot`*Stacked Plots of Multichannel Sequences and/or Most Probable Paths  
from Hidden Markov Models*

---

**Description**

Function `ssplot` plots stacked sequence plots of sequence object created with the `seqdef()` function or observations and/or most probable paths of `hmm` objects.

**Usage**

```
ssplot(  
  x,  
  hidden.paths = NULL,  
  plots = "obs",  
  type = "d",  
  tlim = 0,  
  sortv = NULL,  
  sort.channel = 1,  
  dist.method = "OM",  
  with.missing = FALSE,  
  missing.color = NULL,  
  title = NA,  
  title.n = TRUE,  
  cex.title = 1,  
  title.pos = 1,  
  with.legend = "auto",  
  ncol.legend = "auto",  
  with.missing.legend = "auto",  
  legend.prop = 0.3,  
  cex.legend = 1,  
  hidden.states.colors = "auto",  
  hidden.states.labels = "auto",  
  xaxis = TRUE,  
  xlab = NA,  
  xtlab = NULL,  
  xlab.pos = 1,  
  ylab = "auto",  
  hidden.states.title = "Hidden states",  
  yaxis = FALSE,  
  ylab.pos = "auto",  
  cex.lab = 1,  
  cex.axis = 1,  
  respect_void = TRUE,  
  ...  
)
```

**Arguments**

<code>x</code>	Either a hidden Markov model object of class <code>hmm</code> or a state sequence object of class <code>stslist</code> (created with the <code>TraMineR::seqdef()</code> function) or a list of state sequence objects.
<code>hidden.paths</code>	Output from <code>hidden_paths()</code> function. Optional, if <code>x</code> is a <code>hmm</code> object or if <code>type = "obs"</code> .
<code>plots</code>	What to plot. One of <code>"obs"</code> for observations (the default), <code>"hidden.paths"</code> for most probable paths of hidden states, or <code>"both"</code> for observations and hidden paths together.
<code>type</code>	The type of the plot. Available types are <code>"I"</code> for sequence index plots and <code>"d"</code> for state distribution plots (the default). See <code>TraMineR::seqplot()</code> for details.
<code>tlim</code>	Indexes of the subjects to be plotted (the default is 0, i.e. all subjects are plotted). For example, <code>tlim = 1:10</code> plots the first ten subjects in data.
<code>sortv</code>	A sorting variable or a sort method (one of <code>"from.start"</code> , <code>"from.end"</code> , <code>"mds.obs"</code> , or <code>"mds.hidden"</code> ) for <code>type = "I"</code> . The value <code>"mds.hidden"</code> is only available when hidden paths are available. Options <code>"mds.obs"</code> and <code>"mds.hidden"</code> automatically arrange the sequences according to the scores of multidimensional scaling (using <code>stats::cmdscale()</code> ) for the observed data or hidden states paths. MDS scores are computed from distances/dissimilarities using a metric defined in argument <code>dist.method</code> . See <code>TraMineR::plot.stslist()</code> for more details on <code>"from.start"</code> and <code>"from.end"</code> .
<code>sort.channel</code>	The number of the channel according to which the <code>"from.start"</code> or <code>"from.end"</code> sorting is done. Sorting according to hidden states is called with value 0. The default value is 1 (the first channel).
<code>dist.method</code>	The metric to be used for computing the distances of the sequences if multi-dimensional scaling is used for sorting. One of <code>"OM"</code> (optimal matching, the default), <code>"LCP"</code> (longest common prefix), <code>"RLCP"</code> (reversed LCP, i.e. longest common suffix), <code>"LCS"</code> (longest common subsequence), <code>"HAM"</code> (Hamming distance), and <code>"DHD"</code> (dynamic Hamming distance). Transition rates are used for defining substitution costs if needed. See <code>TraMineR::seqdef()</code> for more information on the metrics.
<code>with.missing</code>	Controls whether missing states are included in state distribution plots ( <code>type = "d"</code> ). The default is <code>FALSE</code> .
<code>missing.color</code>	Alternative color for representing missing values in the sequences. By default, this color is taken from the <code>missing.color</code> attribute of the sequence object.
<code>title</code>	Main title for the graphic. The default is <code>NA</code> : if <code>title.n = TRUE</code> , only the number of subjects is plotted. <code>FALSE</code> prints no title, even when <code>title.n = TRUE</code> .
<code>title.n</code>	Controls whether the number of subjects (in the first channel) is printed in the title of the plot. The default is <code>TRUE</code> : <code>n</code> is plotted if <code>title</code> is anything but <code>FALSE</code> .
<code>cex.title</code>	Expansion factor for setting the size of the font for the title. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
<code>title.pos</code>	Controls the position of the main title of the plot. The default value is 1. Values greater than 1 will place the title higher.

<code>with.legend</code>	Defines if and where the legend for the states is plotted. The default value "auto" (equivalent to TRUE and "right") creates separate legends for each requested plot and positions them on the right-hand side of the plot. Other possible values are "bottom", "right.combined", and "bottom.combined", of which the last two create a combined legend in the selected position. FALSE prints no legend.
<code>ncol.legend</code>	(A vector of) the number of columns for the legend(s). The default "auto" determines number of columns depending on the position of the legend.
<code>with.missing.legend</code>	If set to "auto" (the default), a legend for the missing state is added automatically if one or more of the sequences in the data/channel contains missing states and <code>type = "I"</code> . If <code>type = "d"</code> missing states are omitted from the legends unless <code>with.missing = TRUE</code> . With the value TRUE a legend for the missing state is added in any case; equivalently FALSE omits the legend for the missing state.
<code>legend.prop</code>	Sets the proportion of the graphic area used for plotting the legend when <code>with.legend</code> is not FALSE. The default value is 0.3. Takes values from 0 to 1.
<code>cex.legend</code>	Expansion factor for setting the size of the font for the labels in the legend. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
<code>hidden.states.colors</code>	A vector of colors assigned to hidden states. The default value "auto" uses the colors assigned to the <code>stslst</code> object (created with <code>TraMineR::seqdef()</code> ) if <code>hidden.paths</code> is given; otherwise colors from <code>colorpalette()</code> are automatically used.
<code>hidden.states.labels</code>	Labels for the hidden states. The default value "auto" uses the names provided in <code>x\$state_names</code> if <code>x</code> is an <code>hmm</code> object; otherwise the number of the hidden state.
<code>xaxis</code>	Controls whether an x-axis is plotted below the plot at the bottom. The default value is TRUE.
<code>xlab</code>	An optional label for the x-axis. If set to NA, no label is drawn.
<code>xtlab</code>	Optional labels for the x-axis tick labels. If unspecified, the column names of the <code>seqdata</code> sequence object are used (see <code>TraMineR::seqdef()</code> ).
<code>xlab.pos</code>	Controls the position of the x-axis label. The default value is 1. Values greater than 1 will place the label further away from the plot.
<code>ylab</code>	Labels for the channels shown as labels for y-axes. A vector of names for each channel (observations). The default value "auto" uses the names provided in <code>x\$channel_names</code> if <code>x</code> is an <code>hmm</code> object; otherwise the names of the list in <code>x</code> if given, or the number of the channel if names are not given. FALSE prints no labels.
<code>hidden.states.title</code>	Optional label for the hidden state plot (in the y-axis). The default is "Hidden states".
<code>yaxis</code>	Controls whether or not to plot the y-axis. The default is FALSE.

<code>ylab.pos</code>	Controls the position of the y axis labels (labels for channels and/or hidden states). Either "auto" or a numerical vector indicating how far away from the plots the titles are positioned. The default value "auto" positions all titles on line 1. Shorter vectors are recycled.
<code>cex.lab</code>	Expansion factor for setting the size of the font for the axis labels. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
<code>cex.axis</code>	Expansion factor for setting the size of the font for the x-axis tick labels. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
<code>respect_void</code>	If TRUE (default), states at the time points corresponding to TraMineR's void in the observed sequences are set to void in the hidden state sequences as well.
<code>...</code>	Other arguments to be passed on to <code>TraMineR::seqplot()</code> .

### Details

This function is deprecated and will be removed in future versions of seqHMM.

---

`stacked_sequence_plot` *Stacked Sequence Plots of Multichannel Sequences and/or Most Probable Paths from Hidden Markov Models*

---

### Description

Function `stacked_sequence_plot` draws stacked sequence plots of sequence object created with the `TraMineR::seqdef` function or observations and/or most probable paths of model objects of `seqHMM` (e.g., `hmm` and `mhmm`).

### Usage

```
stacked_sequence_plot(
  x,
  plots = "obs",
  type = "distribution",
  ids,
  sort_by = "none",
  sort_channel,
  dist_method = "OM",
  group = NULL,
  legend_position = "right",
  ...
)
```

**Arguments**

x	Either a hidden Markov model object of class <code>hmm</code> , <code>mhmm</code> , <code>nhmm</code> , or <code>mhmm</code> , a sequence object of class <code>stslst</code> (created with the <code>TraMineR::seqdef()</code> function) or a list of <code>stslst</code> objects.
plots	What to plot. One of "obs" for observations (the default), "hidden_paths" for most probable paths of hidden states, or "both" for observations and hidden paths together. Latter two options are only possible for model objects.
type	The type of the plot. Available types are "index" for sequence index plots and "distribution" for state distribution plots (the default). See <code>ggseqplot::ggseqplot()</code> and <code>ggseqplot::ggseqdplot()</code> for details.
ids	Indexes of the subjects to be plotted (the default is all). For example, 'ids = c(1:10, 15)' plots the first ten subjects and subject 15 in the data.
sort_by	A sorting variable or a sort method (one of "none", "start", "end", or "mds" for type = "index". Option "mds" arranges the sequences according to the scores of multidimensional scaling (using <code>stats::cmdscale()</code> ). Default is "none", i.e., no sorting. Numeric vectors are passed to <code>sortv</code> argument of <code>ggseqplot::ggseqplot()</code> .
sort_channel	Name of the channel which should be used for the sorting. Alternatively value "Hidden states" uses the hidden state sequences for sorting. Default is to sort by the first channel in the data. If <code>sort_by = "mds"</code> , all channels are used for defining the sorting.
dist_method	The metric to be used for computing the distances of the sequences if multidimensional scaling is used for sorting. Default is "OM" (optimal matching). For other more information and other options, see <code>TraMineR::seqdist()</code> . Transition rates are used for defining substitution costs if needed. Note that not all methods are available for sorting multichannel data.
group	Variable used for grouping the sequences in each channel, which is passed to <code>ggseqplot::ggseqplot()</code> and <code>ggseqplot::ggseqdplot()</code> . By default, no grouping is done, except for mixture models where the grouping is based on most probable clusters (defined by the most probable hidden paths). Grouping by clusters can be overloaded by supplying variable for <code>group</code> or by setting <code>group = NA</code> .
legend_position	Position of legend for each channel, passed to <code>legend.position</code> argument of <code>ggplot2::theme()</code> . Either a vector of length 1, or of length matching the number of channels to be plotted.
...	Other arguments to <code>ggseqplot::ggseqplot()</code> or <code>ggseqplot::ggseqdplot()</code> .

**Examples**

```
p <- stacked_sequence_plot(
  mhmm_biofam,
  plots = "both",
  type = "d",
  legend_position = c("right", "right", "right", "none")
)
```

```
library("ggplot2")
p & theme(plot.margin = unit(c(1, 1, 0, 2), "mm"))
```

---

state\_names

*Get State Names of Hidden Markov Model*

---

### Description

Get State Names of Hidden Markov Model

Set State Names of Hidden Markov Model

### Usage

```
state_names(object)

## S3 method for class 'hmm'
state_names(object)

## S3 method for class 'mhmm'
state_names(object)

## S3 method for class 'nhmm'
state_names(object)

## S3 method for class 'mnhmm'
state_names(object)

state_names(object) <- value

## S3 replacement method for class 'hmm'
state_names(object) <- value

## S3 replacement method for class 'mhmm'
state_names(object) <- value

## S3 replacement method for class 'nhmm'
state_names(object) <- value

## S3 replacement method for class 'mnhmm'
state_names(object) <- value
```

### Arguments

object	object An object of class <code>hmm</code> , <code>mhmm</code> , <code>nhmm</code> , or <code>mnhmm</code> .
value	A character vector containing the new state names, or a list of such vectors in case of mixture models.

**Value**

A character vector containing the state names, or a list of such vectors in case of mixture models.  
The original object with updated state names.

---

summary.mhmm

*Summary method for mixture hidden Markov models*

---

**Description**

Function `summary.mhmm` gives a summary of a mixture hidden Markov model.

**Usage**

```
## S3 method for class 'mhmm'
summary(object, parameters = FALSE, conditional_se = TRUE, ...)
```

**Arguments**

<code>object</code>	Mixture hidden Markov model of class <code>mhmm</code> .
<code>parameters</code>	Whether or not to return transition, emission, and initial probabilities. FALSE by default.
<code>conditional_se</code>	Return conditional standard errors of coefficients. See <code>vcov.mhmm()</code> for details. TRUE by default.
<code>...</code>	Further arguments to <code>vcov.mhmm()</code> .

**Details**

The `summary.mhmm` function computes features from a mixture hidden Markov model and stores them as a list. A `print` method prints summaries of these: log-likelihood and BIC, coefficients and standard errors of covariates, means of prior cluster probabilities, and information on most probable clusters.

**Value**

- `transition_probs`  
Transition probabilities. Only returned if `parameters = TRUE`.
- `emission_probs`  
Emission probabilities. Only returned if `parameters = TRUE`.
- `initial_probs`  
Initial state probabilities. Only returned if `parameters = TRUE`.
- `logLik`  
Log-likelihood.
- `BIC`  
Bayesian information criterion.

- `most_probable_cluster`  
The most probable cluster according to posterior probabilities.
- `coefficients`  
Coefficients of covariates.
- `vcov`  
Variance-covariance matrix of coefficients.
- `prior_cluster_probabilities`  
Prior cluster probabilities (mixing proportions) given the covariates.
- `posterior_cluster_probabilities`  
Posterior cluster membership probabilities.
- `classification_table`  
Cluster probabilities (columns) by the most probable cluster (rows).

### Examples

```
# Loading mixture hidden Markov model (mhmm object)
# of the biofam data
data("mhmm_biofam")

# Model summary
summary(mhmm_biofam)
```

---

summary.mnhmm

*Summary method for mixture non-homogenous hidden Markov models*

---

### Description

Summary method for mixture non-homogenous hidden Markov models

### Usage

```
## S3 method for class 'mnhmm'
summary(object, ...)
```

### Arguments

<code>object</code>	Non-homogeneous hidden Markov model of class <code>mnhmm</code> .
<code>...</code>	Ignored

---

`trim_model`*Trim Small Probabilities of Hidden Markov Model*

---

### Description

Function `trim_model` tries to set small insignificant probabilities to zero without decreasing the likelihood.

### Usage

```
trim_model(  
  model,  
  maxit = 0,  
  return_loglik = FALSE,  
  zerotol = 1e-08,  
  verbose = TRUE,  
  ...  
)
```

### Arguments

<code>model</code>	Model of class <code>hmm</code> or <code>mhmm</code> for which trimming is performed.
<code>maxit</code>	Number of iterations. After zeroing small values, the model is refitted, and this is repeated until there is nothing to trim or <code>maxit</code> iterations are done.
<code>return_loglik</code>	Return the log-likelihood of the trimmed model together with the model object. The default is <code>FALSE</code> .
<code>zerotol</code>	Values smaller than this are trimmed to zero.
<code>verbose</code>	Print results of trimming. The default is <code>TRUE</code> .
<code>...</code>	Further parameters passed on to <a href="#">fit_model()</a> .

### See Also

[build\\_hmm\(\)](#) and [fit\\_model\(\)](#) for building and fitting hidden Markov models; and [hmm\\_biofam\(\)](#) for information on the model used in the example.

### Examples

```
data("hmm_biofam")  
  
# Testing if changing parameter values smaller than 1e-03 to zero  
# leads to improved log-likelihood.  
hmm_trim <- trim_model(hmm_biofam, zerotol = 1e-03, maxit = 10)
```

---

update.nhmm	<i>Update Covariate Values of NHMM</i>
-------------	--

---

**Description**

This function can be used to replace original covariate values of NHMMs. The responses, model formulae and estimated coefficients are not altered.

**Usage**

```
## S3 method for class 'nhmm'
update(object, newdata, drop_levels = TRUE, ...)

## S3 method for class 'mnhmm'
update(object, newdata, drop_levels = TRUE, ...)
```

**Arguments**

object	An object of class nhmm or mnhmm.
newdata	A data frame containing the new covariate values.
drop_levels	if TRUE (default), drops unused factor levels from newdata before creating design matrices.
...	Ignored.

---

vcov.mhmm	<i>Variance-Covariance Matrix for Coefficients of Covariates of Mixture Hidden Markov Model</i>
-----------	---

---

**Description**

Returns the asymptotic covariances matrix of maximum likelihood estimates of the coefficients corresponding to the explanatory variables of the model.

**Usage**

```
## S3 method for class 'mhmm'
vcov(object, conditional = TRUE, threads = 1, log_space = FALSE, ...)
```

**Arguments**

object	Object of class mhmm.
conditional	If TRUE (default), the standard errors are computed conditional on other model parameters. See details.
threads	Number of threads to use in parallel computing. Default is 1.
log_space	Make computations using log-space instead of scaling for greater numerical stability at cost of decreased computational performance. Default is FALSE.
...	Additional arguments to function jacobian of numDeriv package.

**Details**

The conditional standard errors are computed using analytical formulas by assuming that the coefficient estimates are not correlated with other model parameter estimates (or that the other parameters are assumed to be fixed). This often underestimates the true standard errors, but is substantially faster approach for preliminary analysis. The non-conditional standard errors are based on the numerical approximation of the full Hessian of the coefficients and the model parameters corresponding to nonzero probabilities. Computing the non-conditional standard errors can be slow for large models as the Jacobian of analytical gradients is computed using finite difference approximation.

Alternatively, by using the non-homogeneous model via `estimate_mnhmm` you can compute the standard errors of the coefficients using the bootstrap method.

**Value**

Matrix containing the variance-covariance matrix of coefficients.
